Abstract: Diabetes mellitus refers to metabolic disorders whose main characteristic is chronic hyperglycaemia. The cause is either disturbed insulin secretion, insulin resistance, or usually both. MicroRNAs represent a subclass of non-coding RNA molecules that are short in length, about 17-26 nucleotides. Since they are circulant and can be tissue-specific, their use as diagnostic biomarkers or screening for different diseases is currently undergoing deeper studies. It was found that 22 miRNAs were associated with the pathophysiology of T1DM, 34 with T2DM, and 16 miRNAs were identified to be common amongst T1DM and T2DM. All of them were reconfirmed in at least two separate studies.

Keywords: microRNA; diabetes mellitus; insulin resistance; pancreatic β cells; gene silencing

INTRODUCTION

Diabetes mellitus (DM) encompasses a group of heterogeneous diseases characterized by hyperglycemia. The most prevalent forms of disease are Type 1 DM (T1DM) and Type 2 DM (T2DM). IDF has also just confirmed type 5 diabetes. It is reportedly characterized by severe insulin deficiency, mainly caused by undernutrition during childhood or adolescent years [1]. T1DM affects approximately 8.75 million individuals globally, whereas T2DM currently impacts about 6.28% of the world's population, accounting for 80% of all diabetes cases. DM represents a significant health issue both in terms of prevalence and the impact of its chronic complications, which can lead to organ failure (e.g., kidneys, retina, heart) [2-4]. Projections indicate that these values are expected to increase significantly in the coming years [5].

T1DM and T2DM are multifactorial diseases. T1DM is typically diagnosed following extensive destruction of insulin-secreting pancreatic β cells (70-80%) by T lymphocytes, resulting in the presence of self-reactive autoantibodies (T1A-DM). Non-immune mechanisms account for 10-30% of T1DM cases (type 1B - T1B-DM subclass), which are classified as idiopathic T1DM [6-8]. Idiopathic T1DM does not have an autoimmune background. Although it can present with insulin deficiency, this subclass of DM does not have a clear trigger. Fulminant T1DM represents another subclass that is also non-immune-mediated. It manifests by fast β-cell death, which may be caused by environmental and genetic backgrounds [9]. Altered insulin secretion, often paired with insulin resistance, represents the main mechanism involved in T2DM [10].

The predisposition for DM remains only partially understood. With some exceptions, a complex network of genetic and epigenetic factors can predispose individuals to T1DM and T2DM [11-15]. Since 2004-2005, exosomal microRNAs (miRNAs) have been included in the list of factors associated with DM and its chronic complications [16-17].

miRNA biosynthesis

Small RNA molecules (e.g., microRNAs -miRNAs; small interfering RNAs -siRNAs) are synthesized in the nucleus and subsequently transported to the cytoplasm. The origin of the miRNA molecules is a primary transcript that contains hairpin-shaped

structures [18]. The RNase Drosha recognizes and cuts these hairpin structures in RNA, resulting in a miRNA precursor (pre-miRNA) of about 70 nucleotides in length. These molecules exit the nucleus (by means of exportin-5 complex) and in the cytoplasm are recognized and cut at the loop part by the enzyme Dicer [19]. The double-stranded miRNA is then loaded into the Argonaute (Ago) protein complex, and a complete silencing complex is formed, and the miRNA is used as a template for target recognition [18].

These double-stranded RNA molecules are utilized by the RNA-Induced Silencing Complex (RISC) to regulate gene expression [19]. It has been reported that the structural similarity of these miRNA hairpins and anti-Tn-C aptamers indicates miRNA functionality beyond RISC, making them even more sophisticated regulators [20]. The RISC complex acts as a translational repressor or as an mRNA breaker, depending on the number of base pairs that form between base pairs. One miRNA can target multiple genes, and they often return to silence the primary transcript from which they were synthesized.

The silencing process has critical roles in the physiological processes (e.g., cell differentiation, organism development) [21]. The concentration of miRNA was estimated between 1000 copies/ 1000 mm3 cells and around 200 copies/cell (or 166pM). It has been reported in previous studies that the median half-life of miRNA is approximately 5 days, with some exceptions (e.g., miR-155 was reported to have lower stability) [20]. The temporal and spatial deregulation of miRNA expression and the silencing process can result in pathological consequences (e.g., by modulating the expression of pro-inflammatory and pro-apoptotic effectors), which impact disease onset, progression, and severity [18,22]. The possibility of repeated sampling has increased scientists' interest in assessing the potential of miRNAs as biomarkers for malignant (e.g., lung adenocarcinoma, gastric or breast cancers) and non-malignant diseases (e.g., including DM) [23-27]. It should be taken into consideration that the multi-role of these molecules when comprising a panel for clinical usage. Thus, miR-21, miR-326 (e.g., glioblastoma), miR-34a, miR-2a (e.g., hepatocellular carcinoma), miR-155 (e.g., pancreatic ductal adenocarcinoma), miR-23b (e.g., melanoma, prostate cancer), miR-98 (e.g., squamous cell carcinoma; head and neck carcinoma), miR-186 (e.g., Hodgkin's lymphoma), miR-223 (e.g., chronic myeloid leukemia) were associated with different malignant diseases. But some of these miRNAs were also associated with different nonmalignant diseases (e.g., miR-21- cardiomyocyte hypertrophy; immune response in sepsis; miR-326 and miR-186 - multiple sclerosis; miR-590- extrinsic cardiomyopathy, autoimmune myocarditis; miR-223 - hereditary neutrophilia) [28].

STUDY OBJECTIVES

The study aims to perform a bibliometric analysis to evaluate research trends in the field and to identify and characterize miRNAs implicated in DM using curated bioinformatic resources.

MATERIALS AND METHODS

This study was conducted in two main phases: an analysis of the scientific literature and the identification of miRNAs altered in DM based on records in specialized databases.

Bibliometric Analysis. A comprehensive literature search was performed using the Scopus database [29]. The search strategy targeted the Title and Abstract fields with the following keywords: ("hsa-microRNA" OR "hsa-miRNA" OR "microRNA" OR "miRNA") AND ("type 1 diabetes" OR "type 2 diabetes" OR "T1D" OR "T2D") AND ("human" OR "humans" OR "Homo sapiens") NOT ("mouse" OR "mice" OR "rat" OR "rats" OR "murine" OR "animal model" OR "in vivo" OR "non-human" OR "rodent"). The initial search yielded 1730 articles. After excluding irrelevant subject areas (e.g., Engineering, Mathematics, Materials Science, Arts and Humanities, Social Sciences, Physics and Astronomy), 1,707 articles remained. Further filtering by document type (research articles only) reduced the number to 1085. Applying language (English) and publication stage filters resulted in a final dataset of 1051 articles. The literature analysis was conducted using the Bibliometrix R-package (version 4.4.0) and Biblioshiny (version 5.0), which enabled descriptive statistics, thematic mapping, and trend analysis [30]. All analyses were performed in R (version 2025.05.0, Build 496).

MiRBase [31] and TargetScanHuman 8.0 [32] were consulted to check for predicted target transcripts and conservation status of each miRNA. Diseases associated with miRNA were extracted from the Human ncRNA Gene Database [28].

RESULTS

Literature data analysis

The timespan of the analyzed publications was 2008 to 2025. The dataset comprised 1051 documents published across 440 sources, involving a total of 6409 authors and citing 49120 references. The annual growth rate of scientific output was 18.34%. The average age of the documents was 5.34 years, and the mean number of citations per document was 28.12.

Interest in the publication of this data began between 2008 and 2012 (Figure 1). A high increase was noticed from then on until 2015, with a spike from 2016 to 2022.

As for the average number of citations per year, it aligned with the wave of scientific production (Figure 2). The first spike was observed in 2009, followed by a second spike in 2012. A slight rise was noticed again, from 2018 to 2020.

Figure 1: Annual scientific production of data regarding miRNA and DM.

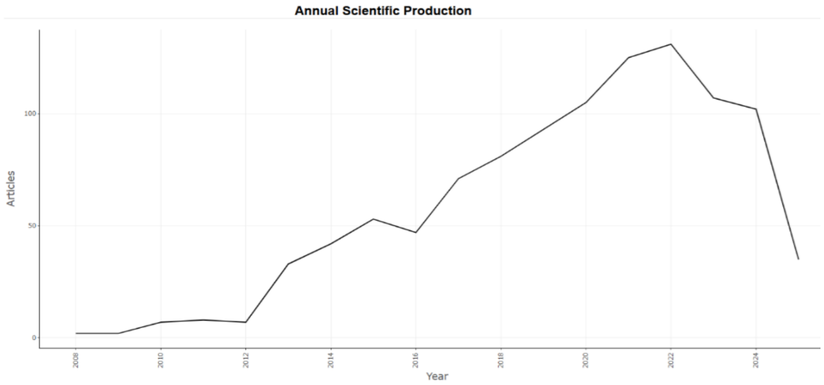

Figure 2: Annual scientific production of data regarding miRNA and DM.

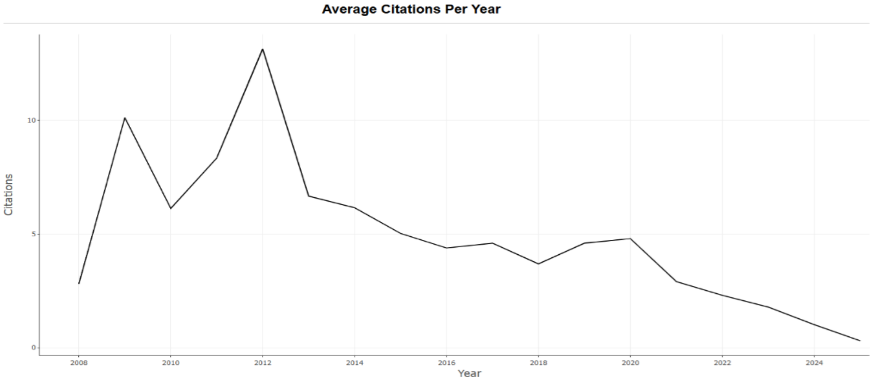

The 1051 articles were published in various sources. The majority of them can be found in PLOS One, Frontiers in Endocrinology, International Journal of Molecular Sciences, and Scientific Reports. Other sources included: Acta Diabetologica, Journal of Clinical Endocrinology and Metabolism, and Molecular Medicine Reports (Figure 3).

Figure 3: Most Relevant Sources containing the included articles.

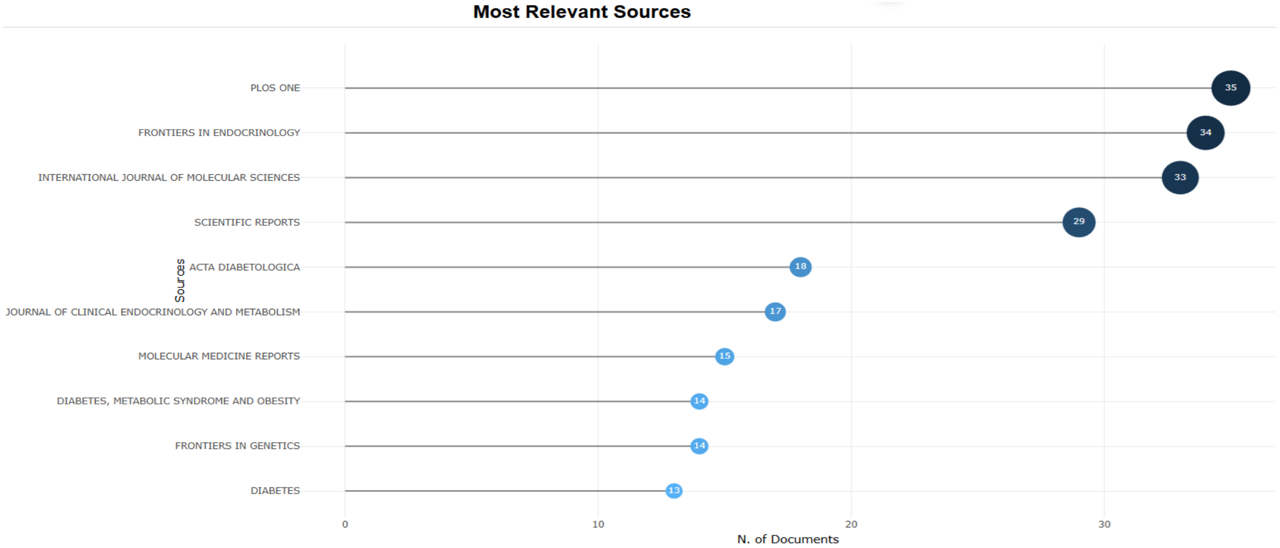

Figure 4: Most relevant authors of articles included in this study.

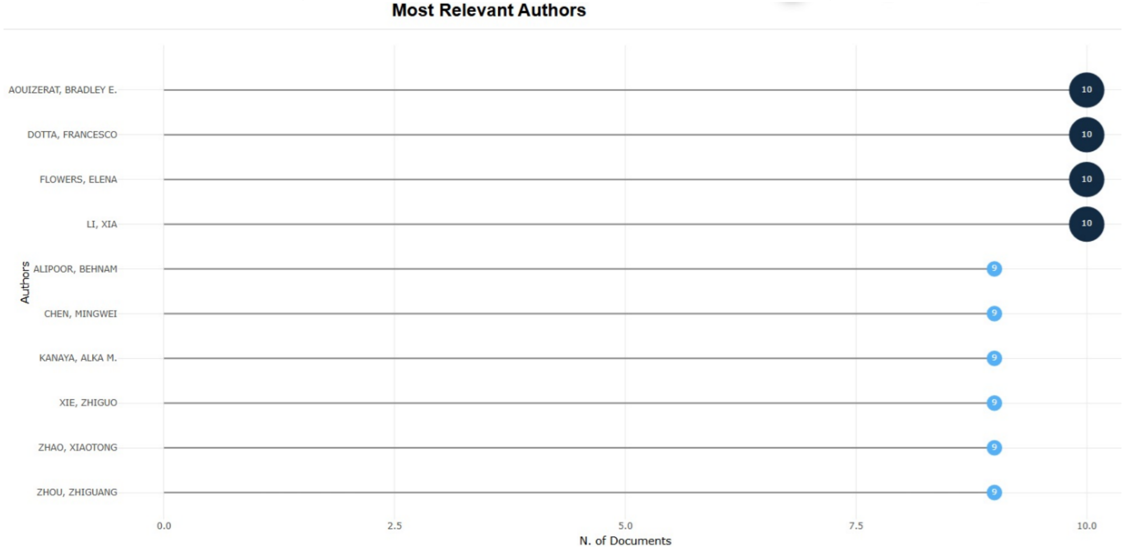

Figure 5: Most relevant affiliations of authors whose papers were cited in this article.

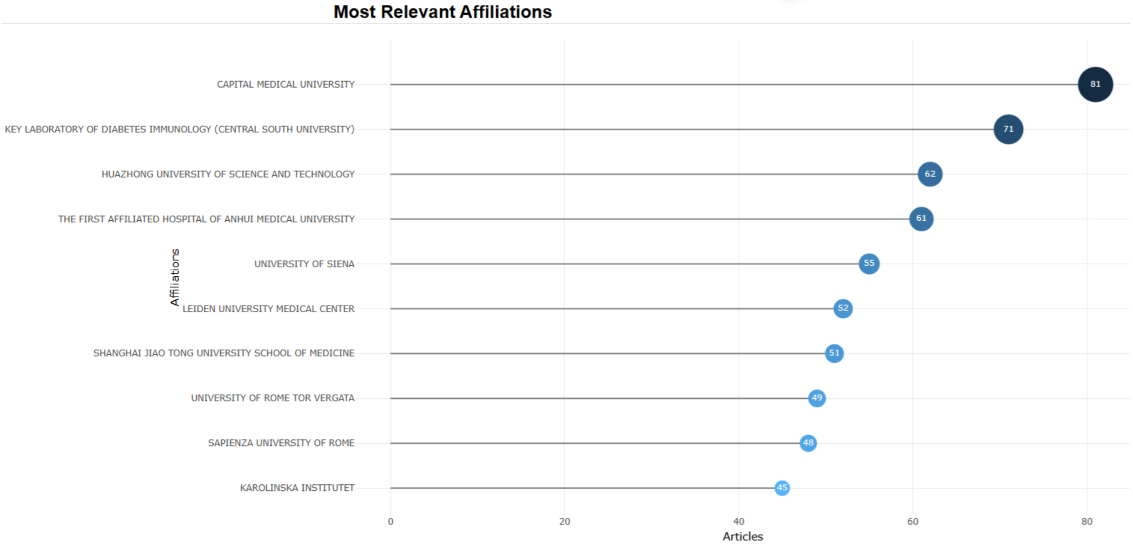

From the 6049 authors who participated in the research included in this paper, some of the most relevant are Dotta F., Flowers E., Li X., Chen M., and Zhao X. (Figure 4). Their affiliations include: Capital Medical University, Key Laboratory of Diabetes Immunology, University of Siena, and Huazhong University of Science and Technology (Figure 5).

Speaking at a global level, the papers with the most citations included in this study were [2,33-36]. The sources in which the works of the aforementioned authors were published include, in order: Oxidative Medicine and Cellular Longevity, Acta Diabetologica, The FASEB Journal, Journal of the American College of Cardiology, and The Journal of Clinical Endocrinology & Metabolism (Figure 6).

The trending topics identified in the reviewed articles highlight the evolving focus areas and emerging themes within the research field over time (Figure 7). Authors' keywords pinpointed in articles that constitute the database change over the years. First time span consisted of keywords such as: “cytokines”, “miR-375”, “single nucleotide polymorphism”. In recent years, keywords such as “diagnosis”, “molecular mechanisms”, “biomarker”, and “type 2 diabetes mellitus” were employed.

The co-occurrence network of authors’ keywords and the microRNA species miR-21, miR-126, and miR-146a highlights the relationship and thematic connections within the literature contained in the database of this paper (Figure 8).

The distribution of corresponding authors by country mirrors the ranking of the most cited countries (Figure 9; Figure 10). Leading the list are countries such as China, the United States, and Italy, which also represent the most active contributors to DM research. In terms of citation impact, Italy is followed by the United Kingdom, Iran, Spain, and Japan.

miRNAs expression and DM

Bioinformatic analysis can be conducted in order to predict possible miRNA targets. Examples of databases constructed for this purpose are miRBase [31], TargetScan [32], and miRecords [37]. For this research, miRbase [31] and TargetScanHuman v8.0 [32] were used for consulting target transcripts and conservation status for each miRNA. Target gene IDs can be found in Tables 1, 2, and 3. MiR ID was normalized according to at least two articles and two miR databases, according to that miR's sequence.

Table 1: microRNAs downregulated (↓) or upregulated (↑) in T1DM analyzed in at least two studies.

miR in T1DM	Target Gene/Mechanism in which they are involved	Referenes
miR-326 ↑	TNFSF14, 15; CEP85	Zheng et. al., 2017
miR-23 ↑; miR-98 ↑; miR-590-5p ↑	Trail, Faslg	
miR-186 ↑	CXCL13; IRF8; STAT4	[38]

TargetScanHuman v8.0 was used to query each miRNA to check predicted target genes.

Some factors involved in the pathophysiology of T1DM (e.g., ILs, tumor necrosis factor) can interfere with the expression of these miRNAs and thereby modulate the efficiency of silencing processes. These observations complicated the relationship between T1DM and miRNAs.

ABERRANT MICRORNA EXPRESSION IN TYPE II DIABETES

Database analysis

MiRNAs can interfere with T2DM physiopathological mechanisms [40] (Table 3). Some of these molecules were associated with both T1DM and T2DM (Table 2).

Although there is significant interest in developing new biomarkers for DM, only a few miRNAs have been consistently associated with T2DM in at least two studies (Table 3).

Table 2: microRNAs downregulated (↓) or upregulated in (↑) T1DM & T2DM analyzed in at least two studies.

DISCUSSION

Literature data analysis

The utility of miRNAs as biomarkers for screening or diagnosis of T1DM is of high interest. There have been some attempts to propose a panel of miRNAs for elaborating these tests, although normalization of miRNA levels is still necessary [47].

A systematic review published in 2017 mentioned 48 miRNAs that were investigate in tissues relevant for T1DM pathogenesis (e.g. serum, plasma, pancreatic tissue, blood cells); for 11 of them the expression level differ significantly in T1DM patients and control subjects (e.g. miR-21-5p, miR-24-3p, miR-100-5p, miR-146a-5p, miR-148a-3p, miR-150-5p, miR-181a-5p, miR-210-5p, miR-342-3p, miR-375 and miR-1275) [22]. There are certain miRNAs (e.g., miR-375) that directly influence specific pathways leading to diabetogenesis. These molecules target genes that modulate immune T cell activity. Human and mouse T lymphocytes have been shown to release exosomal miRNAs (e.g., miR-142-3p, miR-142-5p, and miR-155), which can predispose or support the apoptosis of pancreatic β cells [39]. Additionally, overexpression of some miRNAs can reduce insulin synthesis, insulin secretion, or their biological effects [48].

Cytotoxic attack in T1DM is mediated by proinflammatory cytokines, such as interleukin-1β (IL-1β) and tumor necrosis factor α (TNF-α). These cytokines have been found to induce the synthesis of miR-21, miR-34a, and miR-146a in vitro, in human and mouse pancreatic cells [41].

miR-21 is predicted to target multiple transcripts (e.g., IL12- natural killer cell stimulatory factor and cytotoxic lymphocyte maturation factor, CXCL1- chemokine ligand 1). Increased levels of IL-12 could be predictors of T1DM. IL-12 plays a part in determining the levels of CD4+T cells and increasing the CD8+ T cells' toxicity in DM [49]. It also has a role in activating the apoptotic pathway of the β cells. Existing literature proved the implication of the CXCR1/2 axis, CCL4-CCR5 axis, and CXCL10-CXCR3 axis in the inflammatory background of DM. These pathways were proven to be engaging more aggressive immune T-cells. This furthermore accentuates the β cell death [50].

A decrease in miR-155 expression has been shown to impair the function of regulatory T cells (Tregs), which exhibit an upregulated expression of suppressor of cytokine signaling 1 (SOCS1) upon maturation. Treg cells have a primary role in alleviating the aggressivity of CD4+ and CD8+ T cells. Therefore, their underdevelopment has been linked with one of the causes of T1DM, implicating the STAT3 mutations. The signal transducer was reported to recognize and enhance the miR-155 promoter. The development of Treg cells is also threatened by mutations in the FoxP3 gene, and its altered transcriptional activity has been linked with the presence of miR-155 [51].

The apoptotic genes (Trail, Faslg) are predicted to be targeted by miR-23, miR-98, and miR-590-5p. These miRNAs are overexpressed in CD8+ T cells of T1DM patients [52]. MiR-326 targets different genes (e.g., the gene coding the vitamin D receptor), which modulate the function of the immune system [44]. Expression levels of miR-326 were found to be increased in lymphocytes of T1DM patients who tested positive for the islet-specific autoantibodies IA-2A and GADA [53].

MiR-34a is known to inhibit macrophage polarization, thus impairing tissue homeostasis and repair. This miRNA is involved in the regulation of insulin signaling and glucose metabolism through the targeting of specific mRNAs, including those of sirtuin 1 (SIRT1) and vesicle-associated membrane protein 2 (VAMP2) [54]. Dysregulated miR-34a in cancer patients has been proven to lead to low survival chances. It targets multiple oncogenes and plays a part in apoptosis mediated by the p53 complex, the tumor suppressor gene [55].

In a cross-sectional study, Januszewski and his coworkers demonstrated increased levels of miR-186 and miR-223 in T1DM patients. MiR-186 is known for its role in apoptosis and chemokine and insulin signaling pathways [42]. MiR-186 is also known for being a tumor suppressor in prostate cancer. There was an increase in granulocytes in model mice with miR-223 deficiency, and its expression was highly decreased in patients with active nephritis. This miR-223, along with others, has been associated with multiple cellular processes: p53 pathway regulation, cell cycle regulation, tumor metabolism, and apoptosis [38].

The cumulative roles of miRNAs in T1DM are various, implicating many cellular and molecular pathways and mechanisms. Extensive research is needed to further validate the expression levels in vivo model organisms [47].

miRNAs expression and DM

Certain miRNAs found in scientific publications or databases are associated with the pathogenesis of diabetes or with particular features of diabetic patients. Subjects with impaired glucose tolerance presented abnormal levels of miR-18b [45]. miR-143 has a role in precursor adipocyte differentiation and in predisposition for T2DM (e.g., by targeting the insulin-AKT pathway) [43]. MiR-21 targets mainly FOXO1, FOXA2, and STAT3 transcripts. Its levels were considered informative for gluconeogenesis [56], insulin resistance [57], and altered glucose tolerance [45]. Markers of low-grade inflammation in T2DM (e.g., IL6, TNFα) are also associated with changes in miRNAs. TNFa enhances the intracellular accumulation of miR-223, which targets genes involved in lipid and glucose metabolism, inflammation, and T2DM (e.g., IGF-IR, Hsp90, FOXO1) [58;59].

A randomized community-based study analyzed a sample of 1000 individuals. It was identified several downregulated miRNAs (e.g. miR-126, miR-15a, miR-29b, miR-223, miR-20b, miR-197) in the plasma samples from T2DM patients [46]. Upregulated (e.g., miR-140, miR-142, miR-222) or downregulated (e.g., miR-125b, miR-126, miR-130, miR-192, miR-195, miR-423-5p, miR-532-5p) miRNAs in T2DM patients were also identified in a cross-sectional, double-blinded study. It was observed that the expression levels of four miRNAs (e.g., miR-126, miR-140-5p, miR-195, miR-423-5p) demonstrated a strong ability to distinguish subjects with T2DM from those with normal fasting glucose levels [60]. MiR-126 has been reported by a considerable number of research groups to be a suitable biomarker for the assessment of T2DM progression [44, 46, 61]. MiR-186 expression levels were found to be statistically significantly associated with HbA1C levels in T2DM patients and with the risk of diabetic neuropathy [62].

There are numerous factors to consider when evaluating the potential of miRNAs as biomarkers for DM. For instance, the dynamics of miRNA concentration may be correlated with causes of dysregulated expression (e.g., number of cells releasing these small non-coding molecules or with miRNA overexpression in individual cells), miRNA half-life, and factors influencing their stability. Other factors can also significantly impact the significance of results. For example, an increase in adipose tissue volume can increase the levels of some miRNAs; these associations may influence the results, particularly in studies involving obese patients with T2DM [45]. The timing of miRNA testing poses a challenge, especially in presymptomatic stages of diabetes [63]. It has been hypothesized that dysregulated miRNAs may be present only in specific cells or tissues. Comprehensive research involving paired analyses of body fluids and biopsy tissues, along with validation studies, could be beneficial for future investigations [64]. There also remains a critical need for the standardization of miRNA analysis across different research platforms, tissues, and conditions to facilitate the development of clinically useful biomarkers [65].

The size of the sample pool influences the study's power and the reliability of results. Studies with small sample sizes (e.g., fewer than 10 patients and 10 control subjects) may yield biased outcomes [66]. Consequently, findings from such studies may not be corroborated by research involving larger sample sizes. Therefore, the statistical significance and clinical relevance of some miRNA studies may be limited. Reliable statistics are needed against large sample pools and of different categories.

CONCLUSION

MiRNAs can target a large number of transcripts, and their levels in specific tissues change during the natural history of the disease. But these factors also increase the difficulty of identifying the relevant genes for diabetogenesis and validating the clinical use of specific miRNAs. Standardization in profiling techniques and validation of these biomarkers across large, diverse populations remain essential steps toward their clinical application.

This review underscores the emerging role of miRNA as one of the key molecular players in the pathogenesis, diagnosis, and potential treatment of DM. Numerous studies have identified distinct expression patterns of specific miRNAs (e.g., miR-21, miR-126, miR-143, miR-155, miR-223, and miR-375) that correlate with immune dysregulation, β-cell apoptosis, insulin resistance, and metabolic imbalance.

Conflicts of interest and sources of funding

The authors declare no conflict of interest. This research work was carried out with the support of the Romanian Ministry of Education and Research, under the Core Program, project PN 23 01 03 03. The funders had no role in the design of the study; in the collection, analyses, or interpretation of data; in the writing of the manuscript; or in the decision to publish the results.

Abstract: Effective communication is essential in healthcare, prompting the inclusion of communication courses in medical education. However, the effectiveness of such courses for Romanian medical students has not been evaluated. This pilot study investigates the impact of an ethical communication course on Romanian medical students' communication self-efficacy, communication skills, and the perceived importance of communication. Students attended a 3-month course on ethical communication, covering active listening, assertive communication, conflict management, non-verbal communication, patient-centered care, and ethical considerations in various medical fields. The course was developed based on the European Psychiatric Association guide regarding ethical aspects of communication with patients and their families. The data were analyzed on a sample of 24 students who completed the questionnaires at pretest and posttest. Students reported higher levels of medical communication self-efficacy and perceived importance of medical communication after the course. However, no statistically significant differences were found in health professionals' communication skills. Future courses should include more patient interactions and varied teaching methods. Further research with larger samples and control groups is needed.

Keywords: communication self-efficacy; healthcare communication skills; ethical communication course; healthcare students

INTRODUCTION

Ethical issues are a daily reality in healthcare, affecting both patient care and professionals' well-being. Studies indicate that nurses and physicians frequently encounter dilemmas related to patient autonomy, informed consent, resource allocation, and end-of-life care [1,2,3]. Ethical conflicts often arise when professional values clash with institutional constraints, leading to moral distress and demoralization [4]. The World Medical Association (WMA) International Code of Medical Ethics (2022) and the International Council of Nurses (ICN) Code of Ethics [5] emphasize that healthcare professionals must uphold patient rights, confidentiality, and informed decision-making, yet the ability to navigate these obligations depends on effective communication skills. Nurses, in particular, report high levels of stress and burnout due to ethical conflicts, with staffing shortages and inadequate support being major contributors [3]. Younger and less experienced professionals struggle more with ethical dilemmas, highlighting the need for early training in ethical reasoning and communication during medical education [2].

Without structured guidance, healthcare professionals may feel powerless or unprepared to address ethical concerns, negatively impacting patient trust and care quality. The increasing ethical complexity of medical practice demands that future healthcare professionals receive formal training in ethical communication. Research demonstrates that ethical challenges are frequent and stressful, particularly for younger and less experienced clinicians [2,3]. Demoralization, moral distress, and institutional constraints further complicate decision-making, highlighting the need for early intervention through ethics education [4]. A structured ethical communication course for medical students would provide the necessary skills to navigate ethical dilemmas, improve patient relationships, and support professional integrity in healthcare practice.

Effective communication is a critical tool for resolving ethical dilemmas, reducing stress, and fostering patient-centered care [3,4]. The professionalization of healthcare ethics has gained momentum, emphasizing the need for structured training in ethical decision-making [6]. Ethical communication courses can serve as a preventive strategy against demoralization, equipping students with tools to

navigate ethical tensions proactively. Current medical education often provides limited exposure to ethics beyond theoretical frameworks, leaving students unprepared for real-world ethical dilemmas [4]. Communication skills are considered essential in the healthcare professions, prompting the inclusion of courses aimed at developing these competencies within many medical education programs [7,8]. These courses generally aim to improve students' attitudes towards patient communication (i.e., their perception of the importance of communication skills), to increase students' self-efficacy regarding communication with patients (i.e., their confidence in their ability to communicate effectively), and to improve their actual communication skills [8]. Furthermore, the majority of medical education programs addressing communication skills encompass an ethical dimension related to patient communication [9]. Communication with patients is also a topic of interest for the Romanian academic medical community, with experts in the Romanian healthcare system highlighting the necessity of cultivating students' communication skills [10]. However, the efficacy of such courses for Romanian medical students has yet to be evaluated. To cover this gap, the purpose of the current study is to investigate the effectiveness of a course on ethical considerations in communication with patients for Romanian medical students. Specifically, we examined the course's impact on increasing students' medical communication self-efficacy, health professionals' communication skills, and perceived importance of medical communication.

Previous studies support the effectiveness of courses designed to enhance communication skills with patients. In one study [11], nursing students were trained in communication skills using complex care scenarios, with professional actors portraying patients. The training effectively enhanced self-efficacy and communication skills, with sustained benefits observed 6 months post-intervention. In another study [12], a communication skills training program that included experiential learning methods (e.g., role-playing) and a medical psychology course significantly improved medical students' positive attitudes toward communication skills. A recent research [13] evaluated the acceptability and efficacy of a communication skills training program tailored for nursing students. The program focused on building empathy and discussing complex situations such as end-of-life care. Results indicated that the training significantly improved nursing students' confidence and usage of essential communication skills in complex clinical scenarios. One study found that three experiential teaching methods (practicing patient interviews with peers, followed by debriefing and feedback; conducting interviews with trained actors simulating patients, followed by feedback sessions; watching actors playing a theatrical performance that included communication challenges between doctor and patient) are equally effective in teaching interpersonal communication skills to medical students [14].

In addition to effective communication, recent medical literature emphasizes the importance of ethical competence in protecting patients and promoting high-quality care [15]. It requires a combination of personal virtues, professional ethics, reflective practice, and a commitment to confidentiality and honesty [15,16]. Ethical competence enhances the quality of care and supports healthcare professionals in making ethical decisions [16]. In a systematic review that explored the literature on ethics education aimed at fostering ethical competence among healthcare professionals and students [17], based on the thematic analysis of 40 articles, the review highlights that ethics education is crucial for developing the ability to recognize and manage ethical issues in healthcare settings. Key themes identified include the importance of creating supportive conditions for ethical learning, designing effective educational strategies, and fostering interaction among learners. The studies reviewed indicate that ethics education can help healthcare professionals and students become more aware of ethical problems, enhance their ethical reasoning skills, and ultimately improve their ability to act in the best interests of patients. Indeed, another literature review based on 23 empirical studies [18] revealed that ethics interventions enhanced ethical knowledge, moral sensitivity, and the ability to identify ethical problems among healthcare workers and students. Interventions also improved ethical empowerment, including moral courage and the ability to cope with moral distress.

These findings underscore the importance of integrating comprehensive ethical communication skills training into medical students' education programs. Such training can significantly enhance medical students' confidence and skills, particularly in handling complex and emotionally charged interactions with patients and families, the ability to recognize and manage ethical issues, and ethical reasoning skills. Following this general trend of integrating communication and ethics courses in medical educational programs, the purpose of the current study is to evaluate the effectiveness of an ethical communication course for Romanian medical students in increasing students' medical communication self-efficacy, health professionals' communication skills, and perceived importance of medical communication.

MATERIALS AND METHODS

Participants

No a priori power analysis was conducted, as the pilot study relied on a small convenience sample of available students. As such, the findings should be interpreted with caution, as the limited sample size reduces statistical power and increases the likelihood of both Type I and Type II errors. Fifty-eight healthcare students completed the questionnaire. Five responses were excluded because the participants answered an attention check question incorrectly ("Do you think stones float on water?", Agree/Disagree). One case was excluded due to missing values. The final sample at the pre-test consisted of 42 women (80.8%) and 10 men (19.2%). Of these, 32 (61.5%) previously participated in other communication courses, and 45 (86.5%) did medical practice or volunteering in a hospital or clinic. The pilot study participants had an average age of 20.21 years with a standard deviation of .72. The posttest questionnaire was completed by 24 students. Among them, 16 (66.7%) were women, 8 (33.3%) were men, 21 (87.5%) had previously done medical practice or volunteering in a hospital or clinic, and 11 (45.8%) had participated in a communication course in the past. The students had an average age of 20.25 years with a standard deviation of .67.

To assess potential differences between the students who completed only the pretest and those who completed both the pretest and posttest, we conducted non-parametric and categorical comparisons. A Mann–Whitney U test showed no significant difference in age between the two groups (U = 334.00, Z = –.04, p = .97). However, Chi-square tests indicated significant differences in gender distribution ($\chi^2(1) = 5.71$, p = .02), with a higher proportion of male students among those who completed both assessments. There was also a significant association between attrition and prior participation in communication courses ($\chi^2(1) = 4.65$, p = .03), suggesting that students without previous communication training were more likely to remain in the study. No significant difference was found regarding prior clinical or volunteering experience ($\chi^2(1) = 1.01$, p = .32).

Procedure

The students participated in a 3-month course called Ethical Considerations in Communication with Patients. The first session, called Ethical Communication with Patients and Relatives, included topics such as active listening, assertive communication, conflict management, non-verbal communication, and patient-centered care. The second session, Ethical Communication in Oncology and Palliative Care, included the presentation of the WHO principles of patient care, case studies, and ethical dilemmas. The third session was about ethical considerations in organ transplantation. The fourth session addressed the ethical considerations in communication within the field of psychiatry and mental health. Finally, the last session was about social media, mass media, and public health issues.

The sessions were developed based on the European Psychiatric Association guide regarding ethical aspects of communication with patients and their families [19]. The basic principles of communication that were presented were: respecting the patients' autonomy, dignity, opinions, values, privacy, and confidentiality; sincere and clear communication; encouraging the expression of emotions; using a language adapted to the patient's age and culture; avoiding time constraints [19]. Regarding the communication about the diagnosis, four principles were proposed: informing patients about their diagnosis after analyzing what they know and what they want to know about the disease; the step-by-step and flexible approach to presenting the diagnosis, avoiding the communication of unreliable information; prior discussion with patients to clarify what can be communicated to relatives [19]. Finally, the recommendations regarding communication about treatments were followed: presentation of all relevant information about treatments (risks and benefits, duration, possible adverse events); presenting the advantages and disadvantages of refusing treatment; helping the patient to make an informed decision; informing the relatives about the treatment [19].

Participation in the ethical communication course was optional. Since the present pilot study included only students who voluntarily attended the course, there was no inter-group comparison performed, and variability between groups was not controlled for. The course sessions were delivered by faculty members from the medical university, specifically two psychologists and one psychiatrist with clinical and teaching experience. All lecturers were course coordinators with expertise in communication skills training and medical ethics. The study was conducted in accordance with the Declaration of Helsinki and was approved by the Research Ethics Committee of the University (Approval No. 8371, dated March 29, 2024).

Measurements

Medical communication self-efficacy was evaluated with the scale developed by Parle, Maguire, and Heaven (1997) that measures self-efficacy regarding nine components of communication with the patient (e.g., helping a patient deal with the uncertainty of his/her situation, breaking bad news to a patient) [20]. Students reported on a scale from 0 (not at all confident) to 100 (totally confident) how confident they were that they could successfully manage each situation.

Health professionals' communication skills were measured with the Health Professionals Communication Skills Scale (HP-CSS) [21], which contains 18 items (e.g., When I give information to patients, I do so in understandable terms.) on a scale from 1 (seldom) to 6 (many times) that evaluates four communication skills dimensions (empathy, informative communication, respect, and social ability/assertiveness).

Perceived importance of medical communication was measured with a modified form of the medical communication self-efficacy scale [20], in which the students reported, on a scale from 1 (not important at all) to 5 (very important), how important they consider the behaviors in the respective scale (e.g., concluding a patient interview with an agreed problem list and a plan of action) in the physician-patient relationship.

The instruments were translated into Romanian by two psychologists with expertise in health psychology using the back-translation method. Internal consistency was evaluated using Cronbach's alpha coefficients for each scale at both pretest and posttest, indicating good reliability (values presented in Table 1).

RESULTS

Descriptive Statistics

We performed the descriptive analysis for the study variables at the pretest and posttest for the students who completed the questionnaires at both time points. Results are presented in Table 1.

The Differences between Pretest and Posttest

We analyzed differences between the pretest and posttest using the Wilcoxon signed-rank test. Students reported significantly higher levels of medical communication self-efficacy after the course, Z = –3.29, p = .001, with a large effect size (r = .67). Similarly, the perceived importance of medical communication significantly increased from the pretest to the posttest, Z = –2.26, p = .02, with a medium effect size (r = .46) (Table 2). No significant change was observed in health professionals’ communication skills, Z = –1.72, p = .09, although the effect size was in the medium range (r = .35).

Table 1: Descriptive Statistics for Pretest and Posttest (N = 24)

Variable	Condition	Mean	Standard Deviation	Cronbach's alpha
Medical communication self-efficacy	Pretest	55.99	13.76	.82
	Posttest	68.86	15.83	.89
Health professionals’ communication skills	Pretest	4.70	.61	.86
	Posttest	4.92	.58	.86
Perceived importance of medical communication	Pretest	4.23	.58	.87
	Posttest	4.43	.61	.91

Table 2: The Differences between Pretest and Posttest (N = 24)

Variable	Z	p	Effect size (r)	Interpretation
Medical communication self-efficacy	-3.29	.01	.67	Large effect
Health professionals’ communication skills	-1.72	.09	.35	Medium effect (non-significant)
Perceived importance of medical communication	-2.26	.02	.46	Medium effect

DISCUSSION

This pilot study aimed to assess the effectiveness of an ethical communication course for Romanian medical students in enhancing students' self-efficacy in medical communication, improving health professionals' communication skills, and increasing the perceived importance of medical communication. The course followed the European Psychiatric Association's guide on ethical communication [19]. Key principles included respecting patients' autonomy, dignity, privacy, and confidentiality; clear communication; encouraging emotional expression; using appropriate language; and avoiding time constraints. For diagnosis, principles included informing patients, using a step-by-step approach, avoiding unreliable information, and clarifying what can be shared with relatives. For treatment, recommendations included presenting all relevant information, discussing treatment refusal consequences, aiding informed decisions, and informing relatives.

Ethical communication is increasingly recognized as an essential competency in healthcare, yet many medical students receive inadequate formal training in this area [1,2,3]. Research shows that healthcare professionals frequently encounter ethical dilemmas that require effective communication skills, particularly in cases of informed consent or end-of-life decision-making [4]. The ICN Code of Ethics (2021) and the WMA International Code of Medical Ethics (2022) stress the importance of ensuring clear, transparent, and compassionate communication in patient care, yet studies indicate that many healthcare professionals struggle to implement these principles effectively [3,22]. Ethical stress and moral distress are also common among nurses and physicians who feel unprepared to navigate these complex interactions, leading to demoralization and job dissatisfaction [4]. Given these challenges, structured ethical communication training is essential for enhancing professionalism, patient trust, and ethical decision-making in clinical practice [6].

Students reported higher levels of medical communication self-efficacy and perceived importance of medical communication after completing the course. These results are in line with previous studies in which different types of communication courses had a positive effect on healthcare students’ communication self-efficacy and attitudes toward communication skills [11,12,13]. Our results are also in accordance with the studies highlighting that ethical interventions enhance ethical knowledge [17,18]. Research further suggests that integrating ethics training into medical curricula can reduce moral distress and improve ethical resilience, helping future healthcare professionals navigate value conflicts and ethical dilemmas with greater confidence [2,3].

No statistically significant differences were found in terms of health professionals’ communication skills. This result is in contradiction with other studies in the field [7,13,14,17]. There are two possible explanations for this result. Firstly, without ongoing reinforcement and opportunities to practice these skills in clinical settings, the impact of the course might diminish. It is possible that the students did not have enough opportunities to interact with patients and practice the new skills. Future courses could offer students more practical contexts in which to interact with patients. Secondly, the lack of effect may be because the course did not include didactic methods used in the training that had positive results in increasing communication skills (e.g., care scenarios with professional actors playing the role of patients, practicing patient interviews with peers, watching actors perform a theatrical piece depicting communication challenges between doctor and patient) [11,14]. Future courses could include a greater variety of teaching methods.

The present pilot study has several limitations. First of all, the sample is very small. Second, the study was based on a convenience sample. Thirdly, the sample lacked diversity, as most students shared similar educational backgrounds, age ranges, and academic experiences. This limited representativeness may affect the generalizability of the results to broader and more heterogeneous student populations. Fourth, some of the students did not complete the questionnaire at both time points. Additionally, the voluntary nature of participation may have introduced self-selection bias, as more motivated or engaged students were likely overrepresented in the post-test sample, potentially inflating the observed effects. These limitations regarding the participants make the conclusions of the study inconclusive. Future studies could be based on larger statistically representative samples. Fifthly, there was no control group of students to compare their scores with those of the students who attended the course. Therefore, it was not possible to test whether the increases in self-efficacy and the perception of the importance of communication were due to the participation in the communication course or due to other factors (e.g., the participation in other courses, and the experience with patients in hospitals). Future studies could also include a control group to test the effectiveness of the course. Another limitation of this study is the exclusive use of self-report questionnaires, which are subject to personal biases and may not accurately reflect actual improvements in communication skills. Without objective assessments, such as knowledge tests, role-playing evaluations, or clinical observations, it is difficult to determine whether students have effectively internalized and applied the skills learned. Future research should combine subjective and objective measures to better evaluate training outcomes. In addition, the statistical power of the study was limited due to the small sample size and lack of a priori power analysis. Future studies should conduct formal power calculations to ensure adequate sensitivity for detecting meaningful changes. Finally, although the students participated in the course, they did not have extensive practical experience with patients in hospitals. Therefore, the study participants could not evaluate whether they improved their communication skills in real contexts with patients. Future studies could test the effectiveness of such courses after students have more practical experience with patients. Future studies could also explore the integration of structured pedagogical frameworks (such as experiential or transformative learning models) into course design, to better support behavioral change and deepen students' engagement with ethical communication principles.

CONCLUSION

This pilot study explored the effectiveness of an ethical communication course for Romanian medical students, focusing on its impact on communication self-efficacy, perceived importance of communication, and communication skills. The results indicate that theoretical training can improve students' confidence in communicating with patients and raise their awareness of the ethical significance of medical communication. However, the course did not produce measurable changes in actual communication skills. These findings highlight the need to complement theoretical instruction with practical components such as role-playing, simulations, or supervised patient interactions to support skill development. Given the small, non-representative sample and lack of a control group, the results should be interpreted with caution. Future research should test similar interventions using larger, randomized samples and objective outcome measures. Additionally, future courses could consider incorporating structured pedagogical frameworks to enhance student engagement and better support the internalization and application of ethical communication principles.

Conflicts of interest and sources of funding

REVIEW

Assessment of Suicide Risk in the Civilian Population, Active Military Personnel and Veterans Using Psychometric Instruments – A Literature Review

Octavian Vasiliu[1,2]

Abstract: The assessment of suicide risk is a highly debated topic in the literature due to the complex interplay between social, psychological, cultural, and biological factors that contribute to the pathogenesis of self-harm. There is no unanimously accepted predictive model of suicide and no widely recognized evidence-based algorithm for psychiatric and psychological evaluation in clinical and non-clinical populations for early detection of self-harm. Therefore, this narrative review is focused on identifying the validated clinical instruments that may contribute to the construction of a possible screening and monitoring plan for suicide risk in military and civilian populations. Four electronic databases were searched (PubMed, CINAHL, Google Scholar, and Clarivate/Web of Science) for relevant reports on psychometric tools for detecting suicide risk published between the inception of each archive and January 2025. Seventeen instruments dedicated to the measurement of suicide and suicide-related aspects were reviewed, as well as three tools for the evaluation of depression severity that include specific items for assessing self-harm. The advantages and vulnerabilities of each instrument were assessed, and the particular features of using these tools in the military population were also explored. In conclusion, although a large number of validated instruments for the assessment of suicide risk exist, it is not possible to recommend the use of a single tool, either for clinical and nonclinical populations or for military and civilian personnel. The endeavor of finding an algorithm for the assessment of suicide risk is still far from reaching its end, as new psychometric instruments and possibly a new paradigm for the phenomenon of self-harm are sorely needed.

Keywords: suicide risk, self-harm, depression, military personnel, veterans, suicide prevention

INTRODUCTION

Suicide prevention is one of the most challenging phenomena in clinical psychiatry due to the social impact of self-harm, its high prevalence, and the lack of unanimously accepted predictive models. More than 720000 individuals die by suicide each year, and self-aggression is the third leading cause of death among individuals aged 15 to 29 years old [1]. More than one in every 100 deaths worldwide occurs due to suicide, and methodological improvements are needed in order to increase the accuracy of reports regarding complete suicide and suicide attempts [2]. In this context, structured assessment of suicidal ideation and behaviors is an important aspect of the psychiatric clinical practice, and the development of validated instruments (scales, inventories, and questionnaires) for assessment of suicidal risk is essential for both civilian and military populations.

Suicide rates are still high among military personnel, both active and retired [3]. The Army Study To Assess Risk and rEsilience in Servicemembers (Army STARRS) is a large investigation targeting the prediction of suicide in active duty soldiers who were hospitalized (N=53769 participants), in the next year after discharge [4]. The incidence of suicide in this population was 12% of all US Army suicides, equivalent to 263.9 suicides per 100,000 person-years vs. 18.5 suicides per 100,000 person-years in the entire US Army [4]. This data indicates the need for more careful post-discharge monitoring of active duty soldiers, but the specific means to be implemented for this purpose are far from being clear. A potential contributor to the higher risk of suicide among military personnel has been the existence of stigmatizing beliefs since these can act as deterrents for help-seeking [3]. In a cohort study (N=153,736 patients) of US veterans, the risk assessment suggested that only a few variables were associated with subsequent suicide, especially suicidal ideation, firearm access, and preparatory behaviors, which is completely insufficient to develop a risk prediction algorithm [5]. According to the US Department of Veterans Affairs, the risk of suicide in veterans was 1.57 to 1.66 higher than in non-veterans between 2017 and 2020 [6].

Searching for psychological predictors of suicide is but only one side of the complex process of identifying relevant contributors to the pathogenesis of suicide. Biological factors, such as chronic diseases, and social vulnerability factors, like stigmatization, migration, or bullying, cultural and economic influences, e.g., poverty, acculturation stress, being part of a cultural minority, transgenerational conflicts, etc. [7-12]. However, all these potential pathogenetic factors have intricate relationships, and disentangling them is necessary as part of constructing an evidence-based approach to a predictive model for self-harm behavior.

Based on all these data, it becomes clear that finding adequate tools for detecting the risk of suicide is essential for creating preventative measures and thus decreasing the incidence of completed suicide. To attain this objective, the current review focuses on the detection of the most validated and widely used psychometric instruments for the detection of suicide risk in military personnel, veterans, and civilians. It is expected that such an endeavor could provide the basis of an algorithm for the evaluation of vulnerable populations, as a screening strategy, and for the monitoring of at-risk groups during and after exposure to severe stressors. This review does not target only clinical populations derived from civilian or military environments but also non-clinical populations, which may be exposed to significant risk of suicide ideation and behavior.

MATERIALS AND METHODS

A narrative literature review was conducted by searching four major databases – PubMed, CINAHL, Google Scholar, and Clarivate/Web of Science – for all primary and secondary reports published between the inception of each archive and January 2025, using as keywords “suicide” OR “self-harm” AND “scale” OR “inventory” OR “questionnaire” OR “profile” OR “psychometric instrument” OR “psychometric tool” AND “civilian” OR “military personnel” OR “veterans. Only papers in English were selected. The inclusion criteria were adolescents and adults, clinical and nonclinical groups, civilian and military populations, primary outcomes related to suicide, clinician-rated and self-rated instruments, both prospective and retrospective studies, but also systematic reviews, narrative reviews, and meta-analyses. Exclusion criteria were undefined measurement methods, exclusively non-structured methods of evaluation, poorly defined study design, and children or unspecified population characteristics.

RESULTS

A number of 17 instruments dedicated to the measurement of suicide and suicide-related aspects were found during the literature search, and three tools that include at least one item related to suicide, that were investigated in multiple studies were also included in the analysis.

The **Suicide Attempt Self-Injury Interview** (SASII) was developed by Linehan et al. (2006) to assess the multiple factors associated with suicide attempts and self-aggressive behaviors without a clear suicidal intent [13]. According to the authors of this instrument, its major strength is the use of a standardized definition of suicidal and other self-injurious activities, allowing the practitioners to assess the suicidality/suicide intent regardless of the particular aspects and consequences of the acts themselves [13]. This tool also offers individual ratings for the components of lethality, such as the method used, the consequences of the gesture, and the therapy needed [13]. The scales of SASII are „suicide intent”, „lethality”, „rescue likelihood”, „risk/rescue ratio”, „suicide communication”, „interpersonal influence”, and „emotional relief” [13]. SASII allows for each episode of non-suicidal self-injury behavior to be coded separately and described by its characteristic details. The major variables are assessed by the interview and the frequency of self-injury behaviors, the medical treatment required secondary to the behaviors, and a set of four factors for each episode of non-suicidal behavior - medical risk, suicidal intent, instrumental intent, and impulsivity [13].

A study investigating patients (N=60) with repetitive nonsuicidal self-injury (NSSI) tried to validate subtypes of these behaviors, based on multiple self-report scales, and two structured interviews, SCID-5-CV (Structured Clinical Interview for DSM-5 Clinical Version) and SASII [14]. The results supported a two-subtype model, i.e., (a) substance abuse and suicide attempt subtype- with a higher rate of lifetime suicide plans, number of lifetime suicide attempts, higher severity of self-harm, borderline personality features, anger, posttraumatic manifestations, and difficulties in regulation of own emotions; (b) cutting and scratching subtype [14]. The use of SASII in this study supported the validity of this model and, consequently, the existence of clinical heterogeneity of individuals with NSSI [14].

In another study, SASII was combined with the Beck Scale for Suicide Ideation (BSI), Beck Depression Inventory (BDI), and Beck Hopelessness Scale (BHS), to characterize the self-harm behaviors in a group of Pakistani patients (N=221) [15]. The results showed the possibility of common causal mechanisms and processes underlying self-harm between the investigated population and other groups, with factors such as financial, relationship, or interpersonal difficulties being considered [15]. SASII was administered to collect data on details regarding the time, methods, circumstances, motivations, and treatment for self-harming behaviors [15].

According to a systematic review that explored self-harm measuring tools, seven such validated instruments were identified, but there was a high variation detected in their overall quality [16]. Out of the identified tools, SASII appeared to be the most detailed and psychometrically solid instrument currently available for measuring self-harm behaviors [16]. The other instruments identified were Self-Harm Inventory (SHI), Deliberate Self-Harm Inventory (DSHI), Self-Harm Behavior Questionnaire (SHBQ), Self-Injury Questionnaire (SIQ), Self-Injurious Thoughts and Behaviors Interview (SITBI), and Inventory of Statements About Self-Injury (ISAS) [16]. The reported reliability of SASII was α=0.63-0.93, and the convergent validity with therapist notes (r=0.76-0.86) and the medical records (r=0.75-0.82) were also high [16].

A study investigating the influence of NSSI onset age in adolescents is associated with the frequency of subsequent episodes of self-harm (N=103 participants) showed that a lower age of onset and a longer duration of self-harm were both associated with an increased frequency of other NSSI episodes and a higher risk of a first suicide attempt [17]. Therefore, early identification of NSSI using validated instruments is an essential way to create adequate management strategies for these behaviors [17]. In this important study, SASII was used to collect data on most of the parameters targeted, including time, modality, and frequency of self-harm behavior [17].

A recent cross-sectional study evaluated the presence of factors associated with self-harm behavior during military service in the Israel Defense Forces and used SASII and the Columbia Suicide Severity Rating Scale (C-SSRS) to characterize this population [18]. A number of 1238 episodes of self-harm behavior were identified between 2017 and 2021 and included in the analysis [18]. NSSIs correlated with the presence of adjustment difficulties, and higher rates of previous psychiatric diagnoses were found in individuals with suicide attempts [18]. The risk of dying by suicide during military service was twice as high in soldiers with previous suicide attempts and psychiatric diagnoses [18]. Also, if these soldiers were serving in a combat unit, the risk of suicide was four times higher [18].

Another two-year prospective study explored the predictive value of NSSI for suicide attempts in a clinical sample of US active duty military personnel (N=152, mean age=27.53 years), using SASII and Beck Scale for Suicide Ideation (BSSI-C) [19]. All participants reported current suicidal ideation and/or had a suicide attempt during the last month [19]. The results showed 40% of soldiers with a history of NSSI and 25% of those with a history of suicide attempt made a suicide attempt during the two years of follow-up [19]. Soldiers with a history of NSSI were twice as likely to engage in another suicide attempt, but those with a previous suicide attempt had no increase in suicidal behavior vs. soldiers without a history of suicide attempts [19]. However, 30% of the soldiers with a suicide attempt in their history had engaged in NSSIs, and the total number of NSSIs was significantly associated with an increased risk for future suicide attempts [19].

The **Columbia Suicide Severity Rating Scale** (C-SSRS) is one of the most widely used instruments in Psychiatry to determine suicide risk, but it must be noted that it cannot replace a complete clinical assessment. The C-SSRS has very good convergent and divergent validity with other scales for assessing suicidal ideation and behavior, its subscales are sensitive to changes over time, and the suicidal ideation subscale has a moderately high internal consistency [20]. The C-SSRS is structured in such a way that it allows separate assessments of the severity and intensity of suicidal ideation, autolytic behavior, and lethality of the attempt [20]. The severity of ideation is rated on a five-point scale, the intensity of ideation subscale also on a 5-point ordinal scale (i.e., frequency, duration, controllability, deterrents, and reason for ideation), the behavior subscale is rated on a nominal scale (i.e., aborted, actual, and interrupted attempts, preparatory behavior, and NSSI), while the fourth scale is the lethality subscale for the assessment of actual attempts (there is a 6-point ordinal scale, and if the current lethality is zero, potential lethality of attempts is rated on a 3-point ordinal scale) [20].

The cut-off value of 27 on C-SSRS has very good sensitivity and specificity for classifying suicide attempts in the first three months, according to a prospective multicenter cohort study (N=804 patients with a recent episode of self-harm) [21]. The CSSRS and the Suicide Assessment Scale (SUAS) had a better chance to classify the suicide attempts in the first months but also during a one-year follow-up, although the cut-off value for long-term monitoring could not be established for either instrument [21]. The same study showed that the Suicide Intent Scale (SIS) was the only instrument able to classify suicides adequately at 3 and 12 months, with a cut-off score of at least 21 and at least 17, respectively [21].

C-SSRS had proven a sensitivity of 67% and a specificity of 76% for identifying suicidal behaviors at the follow-up (mean period of 64 days) in a large study (N=3776 patients) [22]. Negative life events were associated with a 2.4% subsequent risk of suicidal behavior, and patients reporting lifetime suicidal ideation with intent/prior suicide attempt had a 4 to 9 times higher risk to report prospectively suicidal behavior [22].

C-SSRS score includes information collected from the patient, but also from other significant sources, and has been validated in emergency settings, as well as in the outpatient population [23]. Also, C-SSRS has been validated in children and adolescents, military veterans, and patients with different psychiatric disorders [23]. The US Food and Drug Administration recommends the use of C-SSRS for clinical trials, and it has been approved by the Centers for Disease Control and Prevention to define and monitor suicidal ideation and behavior [23,24].

The administration of C-SSRS in a large sample of US veterans (N=15373) resulted in confirmation of concurrent validity by comparison with self-reports from the last three months and attempts documented in medical records [25]. Nevertheless, a significant number of discordant responses were reported [25]. The predictive value for future attempts was more than 80% [25]. Another study evaluated the psychometric assessment of C-SSRS and Suicidal Behaviors Questionnaire-Revised (SBQ-R) in 200 active-duty personnel and concluded acceptable reliability for both SBQ-R and C-SSRS ideation severity subscale, while the confirmatory factor analysis supported the SBQ-R, but not the self-reported version of C-SSRS [26]. Yet another study that included US military personnel with lifetime attempted suicide (N=121) used C-SSRS to test the hypothesis that NSSIs elevate the suicide risk; the results showed that a history of NSSI is relevant for increasing the service member's social alienation and acquired tendency for suicide, but did not correlate with the number of lifetime suicide attempts or the controllability of suicide ideation [27].

The **Scale for Suicide Ideation** (SSI) and its self-administered version, Beck Suicidal Ideation Scale (B-SSI), were developed by Beck et al. and are widely used in clinical studies, although their dimensional structure is debated in the literature [28-30]. For SSI, the internal consistency was high, and there were recorded moderately high correlations with clinical ratings of suicidal risk and self-administered measures of self-harm, while the sensitivity to changes in hopelessness and depression over time was also good [28]. For B-SSI, the

Cronbach alpha coefficient was 0.90, indicating high internal consistency for both paper-pencil and computer versions [29]. B-SSI has 21 items, and its items are scored on a 3-point Likert scale, with a total score varying from 0 to 38 [29,31]. The cut-off score of 6 for B-SSI was defined in a prospective study as presenting accuracy for future suicidal behavior, and a reduction to less than eight items with stochastic curtailment was sufficient for this purpose [32]. There is a version for the assessment of current ideation, i.e., the SSI-C, and another for the worst moment in the patient's life, i.e., the SSI-W, both with 19 items [33]. Both SSI-C and SSI-W were positively correlated with a diagnosis of mood disorder, a personality disorder, and measures of depression and hopelessness [33]. The internal consistencies of both scales were high, i.e., alpha 0.84 for SSI-C and 0.89 for SSI-W [33].

A study that involved US military service members showed that summing up five items of the B-SSI (i.e., 1, 2, 4, 6, and 15) is an acceptable strategy to shorten this tool while preserving the predictive value of 74% for a cut-off score ≥1 [34]. A study that included 39 Israeli soldiers (mean age 19 years) who were suicide attempters during their military service included evaluations using B-SSI, C-SSRS, and Suicide Intent Scale (SIS); the results supported seven items of the B-SSI, one of the C-SSRS and two of the SIS were associated with severe suicide attempts [35].

The **Beck Hopelessness Scale** (BHS) explains hopelessness through the concept of a cognitive schema focused on unfavorable expectations, both in terms of the short-term and long-term perspective. This instrument, developed by Beck et al. in 1974, includes 20 items with a dichotomous format, and its primary use is the evaluation of suicide risk in clinical and non-clinical adult populations [36,37]. The original version has three factors, i.e., affective, motivational, and cognitive, but other alternative factorial structures have been suggested [37]. The BHS can be self-administered, as well as administered by the clinician, to hospitalized and non-hospitalized subjects, in specialized outpatient clinics or in emergency hospitals [37]. The predictive validity of BHS has been confirmed by multiple studies in patients with psychiatric disorders [38]. The Cronbach alpha was 0.81 in the general population, according to a study (N=1500 participants) [39]. Shorter versions of BHS have been created, in order to increase its applicability for clinical populations, such as BHS-9 or BHS-4 [38,40,41].

A study focused on improving the detection and prediction of suicidal behavior among military personnel by measuring suicidal beliefs used a set of tools, BHS included, in order to evaluate a new instrument, i.e., the Suicide Cognitions Scale (SCS) [42]. Another study included BHS in the set of instruments dedicated to the assessment of psychological pain in suicidal veterans and concluded that psychological pain accounted for the most shared variance for suicidality, but most relevant correlations were determined for the C-SSRS [43].

The **SAD PERSONS scale** is a mnemonic with each letter representing a risk for suicide, and the total score varies from 0 to 10 [44]. The interpretation is low risk for scores from 0 to 4, medium risk from 5 to 6, and high risk from 7 to 10 [44]. Modified SPS (M-SPS) is characterized by a substitution of new factors and changes in scoring (low risk = 0-5, medium risk = 6-8, and high risk = 9-14) [45]. These are simple and easy-to-administer instruments developed for screening suicide risk in community mental health settings [46].

The SAD PERSONS Scale (SPS) was assessed in a systematic review (N=9 studies) and the data were considered insufficient to support its use in the assessment or prediction of suicidal behavior [47]. In a large study (N=5462 consecutive adults evaluated by psychiatrists in tertiary emergency departments), the suicide rates at six months, 12 months, and five years were determined [48]. Low-risk assessed by SPS at baseline died by suicide at 6 and 12 months, while high-risk scores were significantly associated with death by suicide over the five-year interval by both SPS and M-SPS [48]. Another study (N=4019 consecutive referrals to psychiatric services in emergency departments) used both SPS and M-SPS and showed that high-risk baseline values presented low sensitivity and low positive predictive power [49]. SPS did not predict suicide better than chance in this study, but when only the five original scale items that accounted for the higher proportion of suicide attempt variance were used, the sensitivity was 93.5%, and the predictability was 5-fold higher for suicide attempt presentation [49].

To evaluate the possibility of using SAD PERSONS in veterans, a study (N=271 participants from the Midwest Veterans Affairs Medical Center) concluded that the rate of false-positive and false-negative results is unacceptable [46].

The **Reasons for Living Inventory** (RFLI) was created by M. Linehan in 1983, and it consists of a checklist of motives for choosing to continue living, instead of self-harming with suicidal intent [50]. RFLI has 72 items (long version) or 48 items (short version). The six factors originally describing the structure were replicated by other authors, the internal consistency was proven acceptable (Cronbach alpha = 0.72-0.92), and the test-retest reliability was also demonstrated [51]. A high score on RFLI predicted fewer future suicide attempts in the next two years interval for initially hospitalized women with depression, but not for men, in a study (N=386 participants) [52].

RFLI was administered in a veteran male population (N=421) with various combat exposures and a history of suicide attempts, and the initial results were supportive of this tool being used in the specified population [53]. The reliability and validity of RFLI were confirmed by exploratory factor analysis and bi-factor analysis, correlates between total scores and subscale scores, and estimates of internal consistency reliability on the original instrument subscale scores [53].

The **Reasons for Living Scale-Military Version** (RFL-MV) was created later by Deutsch & Lande, who added 20 items to the items of RFLI-SV, items specifically designed to reflect the military environment characteristics [54]. RFLI-MV was evaluated on 200 patients from the military personnel, and a six-factor structure was defined, with the subscale of "Military Values" reflecting the coherence of the new dimension added to Linehan's version of the tool [54].

The **Reasons for Living versus Reasons for Dying Assessment** is another tool that combines the protective factors and triggers for suicide, to offer a more complete interpretation of the individual's risk [55]. In a study (N=49 suicidal university counseling center patients), 173 reasons for living and 145 reasons for dying were obtained and structured in eight and, respectively, nine categories, and different chi-square results for the two dimensions were obtained, suggesting a different salience of those dimensions for suicidal patients [55]. The evaluation of the reasons for dying vs. reasons for living (RFD-RFL) index in military psychiatric inpatients (N=167) following a suicide event showed that family was the most reported supporting factor (40% of the participants), while the most frequently invoked reasons for dying were general descriptors of self (27%), general statements about escape (19%), and others/relationships (19%) [56]. Higher values of this index were associated with a more significant wish to die vs. wish to live, higher levels of hopelessness, and a history of multiple suicide attempts [56]. When individuals can find more reasons for dying than for living, this could be indicative of a higher suicide risk [56].

Another study evaluated the risks of dying vs. the risks of living in patients admitted after a suicide attempt (N=60) and a monitoring period of 24 months, showing that the number of reasons for dying was the most relevant predictor for increased suicidal ideation at baseline, and reasons for dying, depressive symptoms and baseline suicide ideation predicted suicide reattempt up to 12 months later [57]. In the mediation analysis, reasons for dying mediated the effect of depressive symptoms at baseline and one-year follow-up on suicidal ideation [57]. However, reasons for living did not prove themselves a protective factor against suicide risk [57].

The **Suicide Opinion Questionnaire** (SOQ) was designed to assess the different approaches to the event of suicide in different cultures and demographic groups, being administered in multiple settings and populations, e.g., college students, medical students, and mental health professionals [58,59]. The test-retest reliability coefficient for SOQ was r=0.78 to 0.91, and the intercorrelations between the scales were in the range of r=0.20 [59]. An exploratory factor analysis detected a weak 2-factor structure in one study, and this model failed in the second study, thus raising doubts about the factorial structure of this instrument [60].

In a group of undergraduate volunteers (N=738), the responses to SOQ were compared between attempters, contemplators, and nonattempters, and a factor analysis indicated the existence of seven factors, with two significant functions discriminating between the respondents based on their gender and prior suicide history [61]. In another study (N=91 psychiatric inpatients admitted for suicidality), the SOQ was included in a battery of tests focused on suicidality, and the results showed that 20 items differed between patients with suicide attempts vs. those without at baseline and follow-up [58]. The linear discriminant analysis supported the sensitivity and specificity of the test for post-discharge suicide attempts for the 9-item scale [61]. The potential of SOQ to be useful in identifying prospectively the individuals with a risk of suicide is supported by the available data, but maybe including it in a module of tests would be more beneficial than using it alone, and using it in high-risk patients would increase its predictive power [58].

In a study (N=1758 Marine Non-Commissioned Officers) that evaluated the usefulness of SOQ in military personnel, a 4-factor structure was detected, which accounted for approximately 30% of the total variance, with sex, education, and prior exposure to suicide within the individual's military unit being significantly associated with suicide options [62].

The **Suicide Trigger Scale** (STS) is a self-report instrument to assess the trigger states for suicide, which showed a strong internal consistency, with a Cronbach alpha of 0.94, and good validity related to past suicidal behavior [63,64]. Its third version, STS-3, showed that scores may be predictive for post-discharge suicide attempts [63]. This scale has 42 items and three factors explaining 43% of the variance- Frantic Hopelessness, Ruminative Flooding, and Near-Psychotic Somatization [64]. In a validation study (N=183 adult psychiatric patients with suicidal ideation/attempt in the psychiatric emergency room) with a 1-year follow-up, suicidal subjects with suicide attempt history had a mean of 7 points more than those without such a history, and Frantic Hopelessness was a significant predictor for current suicide attempt, if only attempters requiring at least some medical attention were considered [64].

A subset of six items on the STS-3 improved the prediction of post-discharge suicide attempts, and patients with ultra-high scores differed significantly from those with ultra-low scores on mood intensity, depression, impulsiveness, abuse history, and attachment security, in a validation study (N=161 adult psychiatric patients admitted to hospital for suicidal ideation or attempt) [63].

The **Manchester Self-Harm Rule** (MSHR) was based on an exploration of multiple variables related to self-harm, i.e., those which include the nature of the act, details of self-harm episode, the main reason for current distress/precipitant to the episode of self-harm, social and demographic information, clinical history, and current medical state [65]. The four questions of MSHR refer to the history of self-harm, previous psychiatric treatment, current psychiatric treatment, and benzodiazepine taken as an overdose [65]. The tool has a sensitivity of 97%, a specificity of 26%, and a positive predictive value of 22% [65]. A related tool is the ReACT Self-Harm Rule, derived from a prospective cohort study, which analyzed 29571 self-harm presentations to hospital Emergency Departments [66]. Recent self-harm (in the last year), living alone/homelessness, cutting as a method of self-harm, and treatment for an ongoing psychiatric disorder were factors associated with higher risk [66]. This tool had 95% sensitivity and 21% specificity, with a positive predictive value of 30%, identifying 83 out of the subsequent 92 suicides [66].

The **Suicidal Behaviors Questionnaire** (SBQ) is a 34-item self-assessment instrument for suicidal thoughts and behaviors, developed by Linehan in 1981 [67]. Another, much shorter form of SBQ, containing only four items, and another 14-item tool [67-60]. Other versions of SBQ are available, but this multitude of variants precludes the finding of definite recommendations and psychometric properties for each population (adolescents vs. adults, clinical vs. nonclinical) [70,71]. SBQ 4-item version correlated with SSI scores significantly and it is recommended as a screening tool [71]. A revised version exists, SBQ-R, with four items, which benefits from empirical support as a risk measurement tool that differentiates between suicide-risk and non-suicidal risk individuals at a cut-off value of 7 (nonsuicidal sample) or 8 (clinical samples) [70]. SBQ-R has good internal consistency (Cronbach alpha = 0.97), convergent validity, a one-factor solution (89.5% of the total variance), good sensitivity (82%), and specificity (63%) when differentiating between serious planner/ideator and attempter groups [70]. SBQ-R has been translated and validated in numerous languages due to its brevity, ease of administration, and good psychometric properties [72,73].

The first item ("Have you ever thought about or attempted to kill yourself?") of the SBQ-R and the total scores have been recommended for use in both clinical and non-clinical populations [70]. A Bayesian approach to the SBQ-R supports the usefulness of item 1 for identifying other parameters of suicide, e.g., thoughts and behaviors [74]. The same analysis showed the relevance of each SBQ-R item when exploring the suicide elements and suggests that the individual item evaluation can offer clinically meaningful insights [74].

SBQ-R and the Risk-Taking Questionnaire 18 (RT-18) helped differentiate between individuals with suicide attempts and healthy controls by the variable "risk-taking" [75]. Individuals who reported a recent suicide attempt also had a higher tendency to sensation-seeking and impulsive behavior as correlates to risk-taking behaviors [75]. SBQ-R and other instruments were administered in a study (N=1310 medical graduate students) that suggested a significant risk of suicide (6.7%) among specific populations of students in China [76]. Poor relationships with the supervisor increased the risk of suicidality, suggesting more care is needed when educators are interacting with medical students, especially if the last ones are coming from families with low socio-economic status [76]. The administration of the original SBQ version in clinical populations was also explored in a study with patients diagnosed with bipolar disorder (N=98 participants); the association between anxiety dimensions and SBQ scores was relevant in a similar way to the association with depressive rumination [77]. Depressive rumination was a significant predictor of higher SBQ scores, and emotional processing was a significant predictor for lower SBQ scores for women and the entire sample [77].

In an exploration of the temperament dimensions most associated with the progression from ideation to suicide attempts, an adapted version of SBQ with 17 items was used together with the Affective and Emotional Composite Temperament Scale (AFECTS) [78]. The depressive, cyclothymic, and volatile were the most frequently associated temperaments with suicide attempters, while the cyclothymic, depressive, and euphoric temperaments were associated more with progression from ideation to suicide attempt [78].

The use of SBQ-R in a study that included post-9/11 veterans and service members seeking treatment for psychiatric symptoms (N=261 participants) reflected the high rates of suicidal ideation and behavior in this population [79]. A rate of 40% was obtained in this sample, based on the SBQ-R, indicating a high risk of suicide [79]. Negative posttraumatic thoughts about self, gender, military branch of service, higher levels of severity, anger and anger expression, less impulse control, and lower rank, all these factors were associated with a higher risk of suicidal ideation and behavior [79].

Another retrospective analysis included 3356 cases (age 55+) collected from the US National Health and Resilience in Veterans Study (2019-2020) and used SBQ-R in correlation with various demographical and personal history data [80]. The rate of suicidal ideation during the last year was 6.6%, for lifetime suicide plans was 4.1%, and for future suicide intent 0.9% [80]. A higher level of loneliness and a lower level of purpose in life was most strongly associated with last year's suicide ideation, while a lifetime history of major depressive disorder correlated with suicide plans and suicide attempts [80].

In another cohort study (N=3078 US military veterans), the rates of suicide ideation and suicide attempts did not present higher values during the COVID-19 pandemic vs. pre-pandemic level, but a small percentage of veterans (2.6%) developed new-onset suicidal ideation during the pandemic [81]. SBQ-R items 1 and 2 were used in this study, together with the UCLA Loneliness Scale, Alcohol Use Disorders Identification Test, Life Events Checklist for DSM-5, Adverse Childhood Experience Questionnaire, Medical Outcome Study Social Support Scale-5, and the Coronavirus Health and Impact Survey [81].

The **Military Suicide Attitudes Questionnaire** (MSAQ) is a 32-item instrument with a four-factor structure designed to be used by military service members [82]. The confirmatory analysis included 317 US military personnel, and good levels of test-retest reliability were found; the four factors identified were "individual-based rejection vs. acceptance", "psychache vs. pathological", "unit-based acceptance vs. rejection", and "moral vs. immoral" [82]. The validation study did not control for social desirability, which may be an important limitation [82].

Two different studies of MSAQ validation included 200 and 1116 individuals, respectively, from the military environments, and factorial analyses support the previously reported four-factor structure [3]. The reliabilities ranged from 0.77 to 0.83; men had more negative suicide-related beliefs vs. women, and discomfort and unacceptability beliefs were more positively associated with perceived barriers to care [3].

The **Suicide Probability Scale** was developed in 1982, it contains 36 items and is a self-report tool [83]. This scale was designed to assess suicide risk in adolescents and adults, and it only takes 5 to 10 minutes to complete [83]. The score is obtained by adding the answers using a 4-point scale; there are four factors: Hopelessness, Suicide Ideation, Negative Self-evaluation, and Hostility [83]. The Cronbach alpha for this scale was 0.92 in a sample of hospitalized patients with psychiatric disorders, and the results correlated with the scores on the Beck Depression Inventory-II and Adult Suicidal Ideation Questionnaire [83,84]. The utility of this scale did not confirm its utility in adolescents to assess suicide potential, and the factorial structure was not confirmed [85]. However, other studies support its utility for this population, with good convergent and discriminant validity [86].

The **Sheehan Suicidality Tracking Scale** (SSTS) has a standard version with 16 items that assess the seriousness of suicidality, the frequency of key phenomena, and the overall time spent in suicidality on a Likert scale (0-4) [87]. It is available in a patient and clinician-rated format, but a version that reconciles the eventual discrepancies between the previous two in specific items also exists [87]. There is a clinically meaningful change version of the SSTS and a pediatric version (P-SSTS) [87,88]. Another version of SSTS (v.10) has an 8-item instrument that measures variables related to self-injury, self-harm, suicide ideation and suicide attempt, with each item being scored on a Likert scale, from 0 (absent) to 4 (extremely) [89]. SSTS proved good convergent, divergent, internal consistency, and test-retest stability, according to a cross-sectional study (N=303 undergraduate students) [89]. All SSTS items were loaded on a single factor, suggesting it could be useful as a screening tool [89].

In a clinical study (N=82 subjects with generalized anxiety disorder) that assessed an experimental corticotropin-releasing factor antagonist vs. placebo and an active comparator (escitalopram), SSTS had a good sensitivity, as well as item 3 on the Hamilton Depression Rating Scale for Depression (HAMD) for identification suicidal thoughts or behaviors (100% and 63%, respectively) [90].

In another clinical trial, which investigated the evolution of depressive symptoms during citalopram + lithium vs. citalopram + placebo (N=80 patients), SSTS and Montgomery Asberg Depression Rating Scale (MADRS) were administered as primary measures, and the results showed a larger reduction on SSTS vs. MADRS (43% vs. 25%) [91]. A subgroup of patients who received lithium and citalopram had higher SSTS remission rates (45% vs. 19%) [91].

The **InterSePT scale for suicidal thinking** (ISST) has 12 items and assesses the current suicidal ideation in patients with chronic psychosis [92]. In two studies, with 22 inpatients with schizophrenia and schizoaffective disorders who had a recent suicide attempt or ideation, and 980 patients with the same disorders and a history of suicidal ideation in the past 36 months, respectively, ISST was used as a monitoring tool for two years, together with Clinical Global Impression for Severity of Suicide (CGI-SS), Calgary Depression Scale (CDS), Scale of Functioning (SOF) and Positive and Negative Symptom Scale (PANSS) [92]. The Cronbach alpha was high (0.86-0.89) for individual items, as well as the overall value (0.88) [92].

The ISST total score was highly correlated with the CGI-SS by the blind rater [92]. During the InterSePT trial that evaluated clozapine efficacy, ISST and CDS were administered to predict suicide attempts or hospitalizations [93,94]. The results of the InterSePT trial suggest both tools may be useful for assisting clinical decision-making regarding the suicide risk in patients with chronic psychoses [93].

The **Acquired Capability for Suicide Scale** (ACSS) is a 20-item tool administered based on the Interpersonal Psychology Theory of Suicide and assesses factors that facilitate individuals to acquire the ability to engage in suicidal acts, such as fearlessness about death and habituation to pain (which are considered needed to overcome the self-preservation reflexes) [95]. The items are scored on a Likert scale, from 0 to 4, and the reliability of the scale was calculated in a study to be alpha=0.80 [95]. In a study that included suicide ideators, depressed suicide attempters, and control participants (N=44 participants), based on the ACSS administration, suicide attempters showed the highest level of fearlessness and pain insensitivity and a greater history of painful and provocative life events [96].

A systematic review evaluated the use of ACSS among US military personnel and veteran samples (n=31 studies), and the results, based on a high risk of bias sources, indicated inconsistent findings across studies [97]. The authors of the respective analysis recommended caution in the interpretation of ACSS empirical data [97].

Regarding the instruments for the assessment of depression, which include items specific for suicidality, three tools were analyzed based on their wide use in clinical and epidemiological trials and their validated psychometric profile.

The **Beck Depression Inventory** (BDI) is among the most widely used self-rating scales for depression severity, with a long history of being administered in therapeutic and other various studies, starting from its publication in 1961 [98]. The internal reliability was confirmed in clinical and nonclinical samples and the average Cronbach alpha was 0.75; the factorial validity of this instrument showed a variable number of factors, from 1 to 9, and the convergent and discriminant validity was also proven [98]. Of interest for this review is the suicide item for its predictive value for deaths by suicide, which is scored from 0 (“I do not have any thoughts of killing myself”) to 3 (“I would kill myself if I had the chance”) [99].

A study that included 5319 patients showed that the single BDI item significantly predicted both deaths by suicide and repeated suicide attempts [100]. Each successive rating of the suicide item on BDI conferred greater risk, suggesting a direct proportionality between the two values, with an optimal cutoff score of ≥1 for suicide and ≥2 for suicide attempts providing the maximum equilibrium between sensitivity and specificity [100]. A value of ≥1 on item 9 on BDI-II was also used as a marker for suicide ideation in a study that concluded type D personality could be a risk factor for suicide ideation in individuals with major depression with (N=318) [101].

The **Hamilton Rating Scale for Depression** (HAMD) represents, in fact, a variety of scales that differ by the number of items and modalities of administration [102]. HAMD is a valid and sensitive clinimetric index and requires informed use, with the specific type of HAMD to be selected for each context [102]. The HAMD includes an item on the assessment of suicide risk (scored from 0 – “absent” to 4- “attempts at suicide”) [99]. It correlates significantly with the number of suicide attempts and the age at the first attempt in a study with 281 suicide attempters [103].

The **Montgomery Asberg Depression Rating Scale** (MADRS) is a 10-item tool dedicated to the measurement of depressive severity that includes an item dedicated to „suicidal thoughts” (scored from 0 – „enjoys life or takes it as it comes” to 6 – „explicit plans for suicide when there is an opportunity/active preparations for suicide”) [99]. This item of MADRS and the suicide item on HAMD correlated with the first five items on SSI at a significant level (r>0.80) in a study that assessed the efficacy of ketamine on the severity of depression [99].

DISCUSSION

Table 1 presents a synthesis of the instruments explored in this review. All of the reviewed instruments present benefits and shortcomings, making the unanimous recommendation of only one such instrument for evaluating suicide risk highly unlikely. However, based on the characteristics of each population or group that needs to be explored (screened or monitored) for suicide risk, a certain set of tools may be selected from the available resources, depending on their psychometric properties and previous studies' results available.

Table 1: Analysis of the psychometric tools for the assessment of suicide

Psychometric instrument	Studies on active military personnel and /or veterans	Studies on the civilian population	Advantages	Disadvantages	Observations
SASII	Yes [18,19]	Yes [14-17]	Standardized definition of suicidal and other self-injurious activities; individual ratings for the components of lethality, such as the method used, the consequences of the gesture, and the therapy needed.	More studies on military personnel are needed to confirm its psychometric properties in this population and its predictive power. The necessary time to administer is quite long.	Reliability and convergent validity were determined. Studies that compared this instrument with other validated instruments were performed. Evaluates both suicidal and non-suicidal self-injury behaviors.
C-SSRS	Yes [23,25-27]	Yes [21-23]	Separate assessments of the severity and intensity of suicidal ideation, autolytic behavior, and lethality of the attempt.	Data about the self-reported version of C-SSRS in military personnel is insufficient to recommend its use in this population.	Very good convergent and divergent validity with other scales used for the same purposes.
SSI, B-SSI, SSI-C, SSI-W	Yes [34,35]	Yes [28-20,33]	The set of SSI scales offers a more nuanced choice for different settings and populations.	The dimensional structure is debated.	Good internal consistency and sensitivity to changes for several important suicide factors.
BHS	Yes [42,43]	Yes [38]	Evaluation of suicide risk in clinical and non-clinical adult populations. Self-administered or clinician-administered.		Demonstrated predictive validity and reliability. Shorter versions of this tool have been created.
SPS, M-SPS	Yes [46]	Yes [47-49]	Ease of administration; the existence of a shorter version.	The predictive value of suicidal behavior was considered inconsistent.	A further refinement of the items included in this scale may be needed to increase its predictive value.
RFLI, RFL-MV	Yes [53,54]	Yes [51,52]	A self-administered version and a clinician-administered version exist. A military version of this scale also has been published.	The RFLI scales (both long and short versions) are quite long due to the large number of items.	A checklist of motives for living that can represent useful resources to work with in psychotherapy. Acceptable internal consistency and test-retest reliability.
RFD-RFL Index	Yes [56]	Yes [55,57]	It combines two distinct lists of reasons for living and reasons for dying.	It is a complex and long instrument to administer (17 domains).	Reasons for living are not a valid protective factor against suicide risk. However, reasons for dying may be useful as a predictor of suicide risk.
SOQ	Yes [62]	Yes [58,61]	It was constructed to be sensitive to cultural and demographic variability.	Different studies did not support the factorial structure.	Test-retest reliability was demonstrated. It was administered in different groups. It has the potential to help identify the risk of suicide.
STS	None were identified	Yes [63,64]	It has several versions, some of them presenting scores with good predictive values.	More studies are needed to support its utility, especially in military personnel.	Good internal consistency and validity related to past suicidal behavior. A subset of items could be further explored for higher predictive value than the overall scale.

MSHR	None were identified	Yes [65]	Based on multiple variables related to self-harm	Psychometric properties are poor.	Good sensitivity but poor specificity and low predictive value.
ReACT SHR	None were identified	Yes [66]	Based on a large populational study, and includes multiple variables related to suicide.	More research is needed to validate this instrument.	Good sensitivity but poor specificity and low predictive value.
SBQ, SBQ-R	Yes [79-81]	Yes [70,72,73,75-78]	Many versions of this instrument exist. It was explored in multiple studies that enrolled veterans.	Psychometric properties are poorly defined, except for SBQ-R.	It was extensively explored in both military and civilian populations.
MSAQ	Yes [3,82]	Not applicable	It was explored in two studies with US military personnel.	The currently available studies have methodological limitations.	More studies are needed to explore the validity of this instrument.
SUPS	None were identified	Yes [83-86]	It is a short instrument, easy to administer.	It is a self-report tool. The factorial structure is debated.	Good validity and reliability. The utility of this tool in adolescents to predict suicide was not confirmed.
SSTS	None were identified	Yes [89-91]	Patient and clinician-rated format, and a version that reconciles the differences between the two also exists. A shorter version exists.	No study was identified with military populations.	Good convergent, divergent, internal consistency, and test-retest stability. Only one factor was identified: good screening tools.
ISST	None were identified	Yes [92]	A valuable instrument for assessing suicidal ideation in patients with schizophrenia spectrum disorders.	It applies to a limited population, i.e., a clinical population with chronic psychoses.	High construct validity, good correlation with other scales.
ACSS	Yes [97]	Yes [95,96]	Short, easy-to-administer tool.	Caution is recommended in the interpretation of this scale's results in the military population.	Good validity and reliability.
Scales with single items evaluated for suicide predictive power					
BDI - item 9	None were identified	Yes [99-101]	The suicide item predicted deaths by suicide and suicide attempts.	Insufficient data to support scores on single items as independent predictors of suicide.	Good internal reliability in clinical and nonclinical samples for depressive disorders.
HAMD – item 3		Yes [103]	The suicide item correlated with the number of suicide attempts.		Valid and sensitive tool for depression.
MADRS – item 10		Yes [99]	Short and easy-to-administer tool. The suicide item correlated with items on SSI.		A useful tool for the quantification of depressive symptoms across age intervals.

SASII= Suicide Attempt Self-Injury Interview, C-SSRS= Columbia Suicide Severity Rating Scale, SSI= Scale for Suicide Ideation, B-SSI= Beck Suicidal Ideation Scale, BHS= Beck Hopelessness Scale, SPS= SAD PERSONS, M-SPS= Modified SAD PERSONS, RFLI= Reasons for Living Inventory, RFL-RFD= Reasons for Living versus Reasons for Dying Assessment, RFL-MV= Reasons for Living- Military Version, SOQ= Suicide Opinion Questionnaire, STS= Suicide Trigger Scale, MSHR= Manchester Self-Harm Rule, ReACT SHR= ReACT Self-Harm Rule, SBQ= Suicidal Behaviors Questionnaire, MSAQ= Military Suicide Attitudes Questionnaire, SSTS= Suicide Probability Scale Sheehan Suicidality Tracking Scale, ISST= InterSePT scale for suicidal thinking, ACSS= Acquired Capability for Suicide Scale, BDI= Beck Depression Inventory, HAMD= Hamilton Rating Scale for Depression, MADRS= Montgomery Asberg Depression Rating Scale

A prospective comparative analysis of multiple scales for the assessment of suicide risk included MSHR, ReACT Self-Harm Rule, SAD PERSONS, M-SPS, and Barratt Impulsivity Scale (BIS) in patients who would repeat self-harm within six months [104]. By evaluating 483 episodes of self-harm, the recurrence rate was 30%, and the sensitivity of these tools varied from 1% for SAD PERSONS, to 97% for MSHR [104]. The positive predictive value also varied, from 13% for M-SPS to 47% for the clinician assessment of risk [104]. The authors of the respective study concluded that risk scales for self-harm have limited clinical utility, as they are no better than clinician or patient ratings of risk [76]. A secondary analysis of data collected from multicenter prospective cohort studies showed that some individual items outperformed the scale in which they are included, but no items were superior to clinician or patient risk estimations

[105]. Based on the data from the same analysis, the use of suicide risk scales was less cost-effective than the clinician and patient ratings based on QALY (Quality-Adjusted Life Years) exploration [106].

A systematic review that evaluated the level of evidence for instruments assessing the suicide risk (n=21 studies) included 15 such tools and for the outcome suicide attempt, SPS had a sensitivity of 15% with a specificity of 97%, MSHR 97% and 20%, respectively, ReACT a similarly low specificity with MSHR; BHS presented a sensitivity of 89% and a specificity of 42% for the outcome suicide [107].

A direct comparison of the psychometric properties of CSSRS, STS, and SSTS in 199 psychiatric inpatients was conducted in a randomized manner by three trained judges [108]. All three assessments had very good accuracy for suicidal ideation and attempts (k=0.72 to 1.00, and 0.82 to 0.95, respectively), with an interrater agreement about CSSRS categories being more varied (k=0.48 to 1.00) [108]. Cronbach alpha value was less than 0.55 for CSSRS ideation and 0.78-0.92 for STS and SSTS [108]. The administration of any of these three instruments would improve reliability vs. unstructured assessment in the evaluation of suicidal ideation and behavior [108].

A study included 40 subjects with suicidal ideation and behavior who were interviewed using the InterSePT Scale for Suicidal Thinking-Plus, the SSTS, and the CSSRS, administered in a random sequence [109]. An agreement between these scales and the 2012 Food and Drug Administration (FDA) Classification Algorithm of Suicide Agreement categories was sought [109]. SSTS and InterSePT scale had an acceptable agreement with CSRSS in the detection of passive ideation, active ideation with method, intent, and plan, completed suicide, preparatory actions, and self-injurious behaviors [109]. However, these tools did not detect the presence or absence of other active suicidal ideation combination categories and aborted and interrupted attempts [109]. These results show the importance of validity exploration regarding the widely used scales for suicide risk assessment and the concordance with the FDA categories [109].

The use of single items from validated scales for depression as indicators for the assessment of suicidal ideation is a debated approach in clinical practice. A comparison of BDI and HAMD suicidal items and SSI scores was conducted in 281 suicide attempters and a positive correlation between the first two and the specific scale for suicide scores (SSI) [103].

The importance of searching for chronic diseases as predictors for suicide that can interfere with mental health due to negative impact on multiple levels (i.e., low functionality, poor quality of life, pain, low self-esteem) can not be overemphasized [110-113]. Therefore, any predictive model for suicide should take into account not only personality features, psychiatric symptoms, and actual psychological stressors but also organic diseases and their essential effects on mental health. This involves the necessity of a complex evaluation of individuals with a risk of suicide by a team of specialists, not only psychiatrists and clinical psychologists.

Treatment of the pathological background in patients with suicide risk can not be overemphasized [114-117]. Although significant advances in the field of psychopharmacology can be observed, as well as multiple psychotherapies focused on reducing the risk of self-harm, it is essential to note that no single intervention can be appropriate for all cases with self-harm tendencies, due to the unique configuration of vulnerability factors and triggers that exist in each case.

The current review's limitations are related to its narrative design, which explains why important sources may be missed from the analysis and the lack of assessing the quality of each report. The review's strengths are its focus on clinical tools used for military and civilian populations and the inclusion of psychometric properties together with relevant clinical and epidemiological studies for each instrument.

Directions for further research in this field are the need to further investigate the psychometric properties of some scales presented in this review, like MSAQ, which is dedicated to military personnel, and the comparative exploration of such instruments focused on clinical and non-clinical samples, to highlight the strengths and vulnerabilities of each. The final purpose of further research could be the construction of an algorithm able to detect individuals vulnerable to self-harm behavior.

CONCLUSION

Many good-quality, validated instruments allow for assessing the risk of suicide in civilian populations, and some of them have been explored in military personnel, like SBQ, C-SSRS, SASII, SOQ, etc., while others have been constructed especially for military populations, like MSAQ. Unfortunately, each of these tools has shortcomings that are expected to be corrected by further research.

Therefore, any algorithm for the detection of suicide risk based exclusively on the existing scales, interviews, and questionnaires would be vulnerable to a more rigorous analysis since the complex pathogenesis of the suicide phenomenon would impair its predictability.

Conflicts of interest and sources of funding

The author declares no conflict of interest. No artificial intelligence automatically generated text was inserted in this manuscript, and no image was previously published in another journal or is under consideration of being published elsewhere. This research received no external funding.

Authors' contribution

Abstract: Sepsis remains a leading cause of morbidity and mortality worldwide, with certain high-risk populations—including elderly patients, neonates, immunocompromised individuals, those with chronic diseases, and pregnant women—experiencing worse outcomes. These groups exhibit distinct pathophysiological responses, which complicate diagnosis, treatment, and prognosis. Despite advancements in sepsis management, challenges persist in early risk stratification, individualized therapeutic strategies, and long-term recovery. Aim: This study aims to evaluate the impact of sepsis on high-risk populations, identify prognostic factors influencing clinical outcomes, and explore personalized treatment approaches to optimize patient management. Methodology: A systematic narrative review was conducted, following PRISMA guidelines, by analyzing peer-reviewed literature from 2015 to 2025. This study included the analysis of 80 scientific articles from eight international databases. Studies focusing on sepsis pathophysiology, microcirculatory dysfunction, diagnostic techniques, therapeutic interventions, and post-sepsis outcomes in high-risk populations were included. Results: Elderly patients demonstrated the highest sepsis-related mortality rates (>40%), while neonates and immunocompromised individuals exhibited delayed inflammatory responses, complicating diagnosis. Prognostic biomarkers such as IL-6 and IL-10 showed potential utility in these populations. Personalized fluid resuscitation, antimicrobial stewardship, and immune-modulating therapies were identified as critical to improving outcomes. Post-sepsis syndrome (PSS) was prevalent, particularly in survivors with chronic comorbidities and prolonged ICU stays. Conclusions: Optimizing sepsis management in high-risk populations requires a multidisciplinary, personalized approach, incorporating early biomarker-based diagnostics, precision-guided hemodynamic support, and tailored rehabilitation programs. Future research should focus on novel immunotherapies, antimicrobial resistance strategies, and long-term functional recovery in sepsis survivors.

Keywords: sepsis, microcirculatory dysfunction, prognostic biomarkers, post-sepsis syndrome, antimicrobial resistance

INTRODUCTION

Microcirculatory Alterations in Sepsis

Sepsis is a life-threatening condition characterized by a dysregulated host response to infection, leading to systemic inflammation, multi-organ dysfunction, and, in severe cases, death. One of the critical pathophysiological hallmarks of sepsis is microcirculatory dysfunction, which plays a pivotal role in tissue hypoxia and organ failure [1]. The microcirculation comprises small blood vessels, including arterioles, capillaries, and venules, responsible for oxygen delivery and metabolic exchange at the cellular level [2]. In sepsis, widespread endothelial activation, increased vascular permeability, and impaired autoregulation disrupt normal microvascular perfusion, exacerbating cellular distress and metabolic imbalance [3].

Microcirculatory alterations in sepsis are driven by complex interactions between inflammatory mediators, coagulation disturbances, and endothelial dysfunction. Inflammatory cytokines such as TNF-α, IL-6, and IL-1β induce endothelial cell activation, promoting leukocyte adhesion and microvascular thrombosis [4,5]. Additionally, nitric oxide (NO) dysregulation contributes to an imbalance between vasodilation and vasoconstriction, further impairing tissue perfusion [6].

From a diagnostic perspective, bedside techniques such as sublingual videomicroscopy and sidestream dark-field imaging (SDF) have emerged as valuable tools for assessing microcirculatory abnormalities in critically ill patients with sepsis [7]. These imaging modalities allow real-time visualization of capillary flow, providing essential insights into the extent of microvascular dysfunction and guiding therapeutic interventions. Advanced imaging approaches, including contrast-enhanced ultrasound (CEUS) and near-infrared spectroscopy (NIRS), offer additional perspectives on micro-circulatory heterogeneity and oxygenation deficits in septic patients [8,9].

Understanding microcirculatory impairments in sepsis is crucial for developing targeted therapeutic strategies aimed at restoring tissue perfusion and mitigating organ dysfunction [10]. Recent research has explored the potential benefits of fluid resuscitation strategies, vasoactive agents, and adjunctive therapies such as corticosteroids and endothelial-targeted interventions in optimizing microvascular function.

Fundamental Pathophysiological Mechanisms – Microcirculatory Dysfunction and Endothelial Abnormalities in Sepsis

The pathophysiological mechanisms underlying microcirculatory dysfunction in sepsis are complex and involve a cascade of inflammatory, coagulative, and endothelial disturbances that ultimately lead to impaired oxygen delivery and tissue hypoxia [11].

Microcirculatory impairment is a defining feature of sepsis, characterized by altered capillary perfusion, increased heterogeneity in blood flow, and endothelial dysfunction [12]. Unlike systemic hemodynamic failure, which is typically reflected in macrovascular changes (e.g., hypotension), sepsis-related microcirculatory alterations occur independently of blood pressure changes and directly contribute to organ failure [13].

Inflammation plays a central role in disrupting microcirculatory homeostasis. The excessive release of proinflammatory cytokines such as TNF-α, IL-6, and IL-1β leads to endothelial activation, increased vascular permeability, and leukocyte adhesion to the endothelium [14]. This inflammatory cascade results in endothelial swelling, capillary plugging by activated leukocytes, and microthrombi formation, all of which impede oxygen diffusion and exacerbate tissue hypoxia [15]. Additionally, dysregulated nitric oxide (NO) production contributes to vascular tone abnormalities, creating an imbalance between vasodilation and vasoconstriction that further disrupts blood flow distribution at the microvascular level [16].

From a structural perspective, capillary rarefaction and endothelial glycocalyx degradation are key pathological features of microcirculatory dysfunction in sepsis. The glycocalyx, a protective layer covering endothelial cells, plays a crucial role in vascular permeability and mechanotransduction [17]. In sepsis, glycocalyx breakdown due to enzymatic degradation (by heparanase and matrix metalloproteinases) results in increased vascular leakage, impaired shear stress sensing, and loss of anticoagulant properties, contributing to sepsis-induced coagulopathy (SIC) [18].

Endothelial dysfunction in sepsis is a result of direct cellular injury, oxidative stress, and immune activation. Endothelial cells, which normally maintain vascular homeostasis through the balanced release of vasoactive substances, become dysregulated, shifting towards a pro-inflammatory and pro-thrombotic phenotype [19].

One of the key mechanisms involved in endothelial dysfunction is increased expression of adhesion molecules such as ICAM-1, VCAM-1, and selectins, which facilitate leukocyte adhesion and transmigration into tissues, further amplifying inflammation [20]. This process leads to capillary plugging and increased diffusion distance for oxygen, creating a mismatch between oxygen delivery and cellular demand [21].

At the same time, mitochondrial dysfunction in endothelial cells exacerbates metabolic failure, reducing the ability of microvascular endothelial cells to regulate vascular tone and respond to local oxygen needs appropriately [22]. The resulting endothelial metabolic shutdown contributes to an irreversible cycle of hypoxia, organ dysfunction, and cellular apoptosis in severe sepsis cases [23].

Sepsis-induced coagulopathy (SIC) is a well-recognized phenomenon in which systemic inflammation disrupts the balance between coagulation and fibrinolysis, leading to widespread microthrombosis and perfusion defects [24]. The overactivation of the coagulation cascade is primarily driven by excessive tissue factor (TF) expression, leading to thrombin generation, platelet aggregation, and fibrin deposition within the microcirculation [25].

Additionally, antithrombotic mechanisms become suppressed due to reduced production of key anticoagulant proteins such as antithrombin, protein C, and thrombomodulin, further promoting a prothrombotic state [26]. The resulting microvascular thrombosis impairs capillary perfusion, leading to local ischemia, tissue necrosis, and multi-organ failure in severe septic shock cases [27].

Furthermore, fibrinolytic dysfunction exacerbates these complications. Sepsis induces the release of plasminogen activator inhibitor-1 (PAI-1), which suppresses fibrinolysis and prevents the clearance of microthrombi, further worsening microvascular obstruction

[28]. This shift towards a hypercoagulable state with impaired clot resolution represents a critical therapeutic target in sepsis management.

The long-term impact of microvascular dysfunction in sepsis extends beyond the acute phase of the disease. Persistent endothelial damage and capillary loss contribute to post-sepsis syndrome, characterized by prolonged inflammation, immune suppression, and residual organ dysfunction [29]. Chronic microvascular dysfunction has been linked to long-term cognitive impairment, cardiovascular complications, and persistent fatigue in sepsis survivors [30].

From a therapeutic standpoint, interventions targeting endothelial protection, micro-vascular flow optimization, and early coagulation modulation have shown promise in experimental and clinical studies [31]. Strategies such as glycocalyx preservation (e.g., fluid therapy with albumin, heparan sulfate analogs), endothelial stabilizing agents (e.g., steroids, angiopoietin modulators), and anticoagulant therapy in select patient populations are under investigation for their potential to mitigate sepsis-induced microvascular injury [32].

Prevalence of Microcirculatory Dysfunction in Sepsis

The prevalence of microcirculatory dysfunction in sepsis varies depending on disease severity, patient population, and the diagnostic techniques used. Studies using sublingual videomicroscopy and sidestream dark-field (SDF) imaging have shown that nearly 90% of patients with septic shock exhibit significant microvascular abnormalities, including reduced capillary density, increased flow heterogeneity, and impaired oxygen extraction [33,34]. Even in patients with less severe sepsis, microcirculatory alterations are observed in approximately 50–70% of cases, highlighting the early involvement of the microvasculature in disease progression [35].

The extent of microcirculatory dysfunction is closely linked to the severity of sepsis. In its early stages, microvascular perfusion changes may be subtle while overall hemodynamics remain stable. As sepsis advances to septic shock, severe capillary perfusion defects become more pronounced, leading to increased lactate levels, tissue hypoxia, and multi-organ failure [36].

Certain patient populations are particularly susceptible to profound microcirculatory disturbances. Elderly patients often experience more severe endothelial dysfunction due to age-related vascular changes and a diminished ability to compensate for inflammatory stress [37]. Patients with chronic diseases such as diabetes or chronic kidney disease face a heightened risk due to pre-existing endothelial dysfunction and oxidative stress, which exacerbate sepsis-induced microvascular damage [38]. Immunocompromised individuals, including cancer patients and transplant recipients, frequently exhibit atypical microcirculatory responses due to an altered inflammatory cascade, making early detection more challenging [39].

Microcirculatory dysfunction is significantly more prevalent in sepsis compared to other critical illnesses. In patients with non-septic shock, such as cardiogenic or hemorrhagic shock, global hemodynamic parameters may be compromised, but microvascular function remains relatively preserved in the early stages [40]. In contrast, sepsis induces early and widespread microvascular failure even when macrocirculatory parameters, such as blood pressure, appear normal [41].

In non-septic intensive care unit (ICU) patients, studies indicate that microcirculatory alterations affect only 10–30% of individuals, whereas in sepsis, this prevalence is three to five times higher [42]. This contrast highlights the unique impact of sepsis on the endothelium and microvascular network, making microcirculatory dysfunction a key prognostic indicator.

Special Categories of Patients with Sepsis

Sepsis represents a major challenge in medical practice, but certain categories of patients are at significantly higher risk of complications and mortality. These patients require tailored therapeutic approaches, as they have distinct physiological and immunological characteristics that influence their response to treatment and overall prognosis [43].

Older adults are particularly vulnerable to sepsis due to multiple physiological changes associated with aging. Their immune system undergoes a progressive decline, known as immunosenescence, which is characterised by a reduced ability to respond to infections and impaired production of pro-inflammatory cytokines [44]. Additionally, a state of chronic low-grade inflammation (inflamm-aging) contributes to dysfunctional immune responses, increasing the severity of sepsis.

From a cardiovascular perspective, elderly patients often exhibit increased vascular stiffness and reduced cardiac reserve, limiting their ability to compensate for septic shock [45]. Furthermore, frailty and sarcopenia negatively impact prognosis, increasing the risk of multiple organ failure.

The treatment of sepsis in elderly patients should be individualised, considering their increased risk of cardiovascular overload during fluid resuscitation and their predisposition to acute kidney injury. Close monitoring of haemodynamic status and careful adjustment of antimicrobial therapy based on renal function are essential to improving outcomes.

The presence of chronic diseases affects both the progression and management of sepsis, often complicating treatment strategies and patient outcomes.

Diabetic patients are more vulnerable to severe infections because persistent hyperglycaemia weakens neutrophil function and encourages the growth of resistant pathogens. Additionally, diabetes contributes to endothelial dysfunction, worsening the microcirculatory disturbances typical of sepsis [46].

Patients with chronic kidney disease experience a heightened risk of sepsis as uremia-induced immunosuppression weakens their immune response. The frequent use of vascular catheters further increases infection risks, while the accumulation of uraemic toxins disrupts immune function and slows antimicrobial clearance [47]. These factors make precise antibiotic dose adjustments essential, considering the patient's glomerular filtration rate.

Patients with chronic obstructive pulmonary disease are prone to respiratory sepsis because impaired mucociliary function and chronic airway inflammation promote recurrent infections. Prolonged corticosteroid use, a common treatment for COPD, can further suppress the immune system, making patients more susceptible to opportunistic infections [48].

Managing sepsis in patients with chronic conditions requires a careful approach that balances aggressive therapy with the risks posed by pre-existing diseases. Optimising antimicrobial therapy and fluid resuscitation plays a key role in preventing further deterioration of organ function [49].

Sepsis in children differs significantly from adult sepsis in terms of pathophysiology and clinical presentation. Neonates and infants have an immature immune system, making them more susceptible to severe bacterial and viral infections. Furthermore, infants have a limited ability to mount an effective inflammatory response, potentially delaying the diagnosis of sepsis [50].

Beyond immunological differences, children exhibit major variations in drug metabolism, necessitating careful adjustments in antibiotic and vasopressor dosing based on body weight and organ maturity [51].

Early recognition of sepsis is critical in paediatric patients, as hypotension—a hallmark of sepsis in adults—tends to appear late in children. Identifying early signs of impaired tissue perfusion is therefore essential for the timely initiation of treatment.

Immunosuppressed individuals face a significantly higher risk of severe sepsis and life-threatening complications, often with atypical clinical presentations that can delay diagnosis and treatment [52].

This group includes oncological patients, organ transplant recipients on immunosuppressive therapy, individuals with advanced HIV infection, and patients with autoimmune diseases undergoing biologic treatments. Due to a weakened immune response, sepsis in these patients is frequently caused by opportunistic pathogens, and the usual inflammatory signs may be absent. In cases of severe neutropenia, fever might not be present, making early detection more challenging [53].

Effective management relies on the prompt administration of broad-spectrum antibiotics, close monitoring of inflammatory markers, and immune support when necessary. Granulocyte-colony stimulating factor may be considered to enhance neutrophil recovery and improve outcomes in selected cases [54].

Pregnancy induces significant physiological changes that increase a woman's susceptibility to severe infections and septic complications. Increased placental blood flow and alterations in immune responses can influence both the progression of sepsis and the response to treatment [55].

Sepsis during pregnancy can have devastating consequences for both the mother and the fetus. Intrauterine infections, such as chorioamnionitis, may trigger preterm labour or result in fetal demise. Moreover, maternal hypotension and placental hypoperfusion can severely impact fetal development [56].

The management of sepsis in pregnancy must be prompt and aggressive, with rapid administration of antibiotics that are safe for the fetus and careful monitoring of maternal haemodynamic status. The timing and mode of delivery should be determined through a multidisciplinary approach, balancing maternal and fetal risks.

MATERIALS AND METHODS

This study employed a comprehensive approach to investigate the impact of chronic comorbidities on the progression and management of sepsis. A systematic narrative review methodology was chosen to integrate the structured rigor of a systematic review with a narrative synthesis approach, ensuring a nuanced analysis of a complex, multi-disciplinary topic. The review synthesizes existing literature on the interactions between sepsis and chronic conditions such as diabetes, chronic kidney disease (CKD), chronic obstructive pulmonary disease (COPD), and immunosuppressive states, emphasizing clinical implications and future research directions.

The analysis focused on three key aspects:

Pathophysiological mechanisms underlying increased susceptibility to sepsis in patients with diabetes, CKD, COPD, and immunosuppression, highlighting immune dysfunction, endothelial damage, and microbiome alterations.

Impact of chronic diseases on sepsis outcomes, including prolonged hospitalization, increased mortality risk, and the need for individualized therapeutic strategies.

Optimization of sepsis management in these high-risk populations, exploring antimicrobial stewardship, fluid resuscitation strategies, immunomodulatory therapies, and personalized treatment approaches based on disease-specific factors.

A key question that shaped the direction of this review was: How do chronic comorbidities influence the pathophysiology, clinical presentation, and management of sepsis, and what strategies can optimize patient outcomes in these high-risk populations?

To ensure a systematic synthesis of findings, studies were selected based on predefined inclusion criteria, prioritizing clinical trials, observational research, and meta-analyses that explored sepsis in patients with chronic comorbidities. A comparative evaluation of treatment strategies was conducted, examining the effectiveness and safety of current therapeutic approaches while identifying gaps in knowledge and areas requiring further investigation.

Approach to Identifying Relevant Articles

A systematic literature search was performed across multiple academic databases, including PubMed, Scopus, Web of Science, Elsevier, Springer, Wiley Online Library, MDPI, and Frontiers, to investigate the role of microcirculatory dysfunction in sepsis. The search process adhered to PRISMA guidelines, employing Boolean operators (AND, OR) to enhance search precision and optimize the identification of relevant studies on microvascular changes associated with sepsis.

Key search terms included: "microcirculatory dysfunction in sepsis" (17,100 results), "sepsis-induced endothelial dysfunction" (17,800 results), "capillary perfusion in septic shock" (16,700 results), "microvascular alterations and organ failure" (18,300 results), and "sepsis-associated mitochondrial dysfunction" (10,800 results).

Structured search strings were applied to maximize relevance and retrieve high-quality studies, such as: "(microcirculatory dysfunction OR endothelial dysfunction) AND (sepsis OR septic shock) AND (capillary perfusion OR mitochondrial dysfunction)."

To ensure the inclusion of the most relevant and up-to-date studies, several selection filters were applied. The search was restricted to publications from 2015 to 2025, allowing for the incorporation of both recent developments and foundational research that contribute to the understanding of microvascular dysfunction in sepsis. Only full-text articles available in English were considered to ensure accessibility to studies with broad international relevance.

The review focused exclusively on peer-reviewed literature, including clinical trials, systematic reviews, and meta-analyses. Priority was given to review articles offering a comprehensive synthesis of current knowledge, while clinical studies were evaluated for their insights into the relationships between microvascular dysfunction, disease progression, and treatment outcomes.

Search queries were tailored for each database to account for variations in indexing and search functionalities. Beyond standard database searches, citation tracking and reference analysis of key studies were conducted to identify additional relevant research that may not have been captured in the initial search. This method helped enhance the dataset by incorporating essential studies that might have been overlooked through automated search strategies.

Eligibility Criteria for Study Selection

Inclusion Criteria

The selected studies needed to address the challenges and treatment approaches for sepsis in high-risk patient groups. Included publications were required to provide relevant information on these aspects:

Pathophysiological mechanisms, such as immune dysregulation, endothelial dysfunction, and metabolic alterations in neonates, elderly patients, immunocompromised individuals, and those with chronic diseases.

Diagnostic and monitoring strategies, including biomarkers, advanced hemodynamic assessment tools, and molecular diagnostics for early detection and risk stratification.

Therapeutic approaches, addressing personalized treatment strategies, the role of immune modulation, tailored fluid resuscitation, and organ-support therapies such as renal replacement therapy and extracorporeal membrane oxygenation (ECMO).

The review incorporated original research, systematic reviews, meta-analyses, and clinical studies published in peer-reviewed, indexed journals to ensure the selection of high-quality, reliable sources.

Exclusion Criteria

The following types of studies were not included in the review:

Research that did not adhere to PRISMA guidelines, as standardized reporting is crucial for ensuring methodological reliability.

Case reports that lacked generalizability or did not provide adequate data on sepsis treatment in high-risk patient populations.

Studies that focused only on general aspects of sepsis without addressing the specific challenges faced by neonates, elderly individuals, immunocompromised patients, or those with chronic illnesses.

Articles that were not based on original research or were published in non-peer-reviewed sources were excluded, ensuring that only high-quality, evidence-based studies were considered.

Selection Process

A structured approach was used to evaluate all identified articles based on predefined inclusion and exclusion criteria, ensuring the selection of high-quality, methodologically sound studies relevant to the research objectives. The PRISMA framework was implemented throughout the process to maintain transparency and consistency in study identification. The final selection offers a comprehensive analysis of sepsis patho-physiology, diagnostic methods, and treatment strategies in vulnerable patient populations.

The selection process was carried out in two main stages. In the initial stage, titles and abstracts were screened to determine relevance, prioritizing studies that focused on sepsis in neonates, elderly individuals, immunocompromised patients, and those with chronic conditions. Studies that did not specifically address these populations or lacked original research data were excluded at this point.

During the second stage, a full-text review was conducted on the remaining articles. Preference was given to studies that examined the relationship between sepsis severity, microvascular dysfunction, immune response alterations, and organ failure. Additionally, research discussing tailored treatment approaches—such as immune modulation, hemodynamic stabilization, and organ-support therapies—was prioritized.

To ensure the credibility and reliability of findings, all selected studies underwent a rigorous quality assessment to confirm adherence to PRISMA guidelines and alignment with the research scope. This approach helped minimize potential biases and strengthened the validity of the conclusions drawn.

Despite efforts to create a comprehensive selection, certain limitations must be acknowledged. The exclusion of grey literature may have led to the omission of valuable studies not indexed in major academic databases. Restricting the review to English-language publications may have excluded relevant research available in other languages. Additionally, limiting the search to specific databases may have overlooked studies published in other sources. Lastly, the decision to focus on research published between 2015 and 2025 may have resulted in the exclusion of older foundational studies that could provide historical insights into sepsis mechanisms and treatment advancements.

RESULTS

Overview of Selected Studies

To ensure transparency and traceability in the selection process, a PRISMA diagram has been included in the material, illustrating the number of studies identified and filtered at each stage of the analysis. This diagram initially presents the total number of articles retrieved through the search, followed by the number of those excluded after reviewing titles and abstracts, and finally, the number of studies selected for in-depth analysis. Additionally, the reasons for excluding certain articles are specified, providing clarity regarding the decisions made during the selection process.

The use of the PRISMA diagram is essential for maintaining transparency, as it allows readers to understand the decision-making process behind article selection and ensures compliance with the criteria established at the outset of the review [57,58].

The PRISMA flow diagram in Figure 1 outlines the selection process for studies examining microcirculatory dysfunction and sepsis management in vulnerable patient populations. A systematic search was performed across eight major databases, yielding a total of 80,700 results.

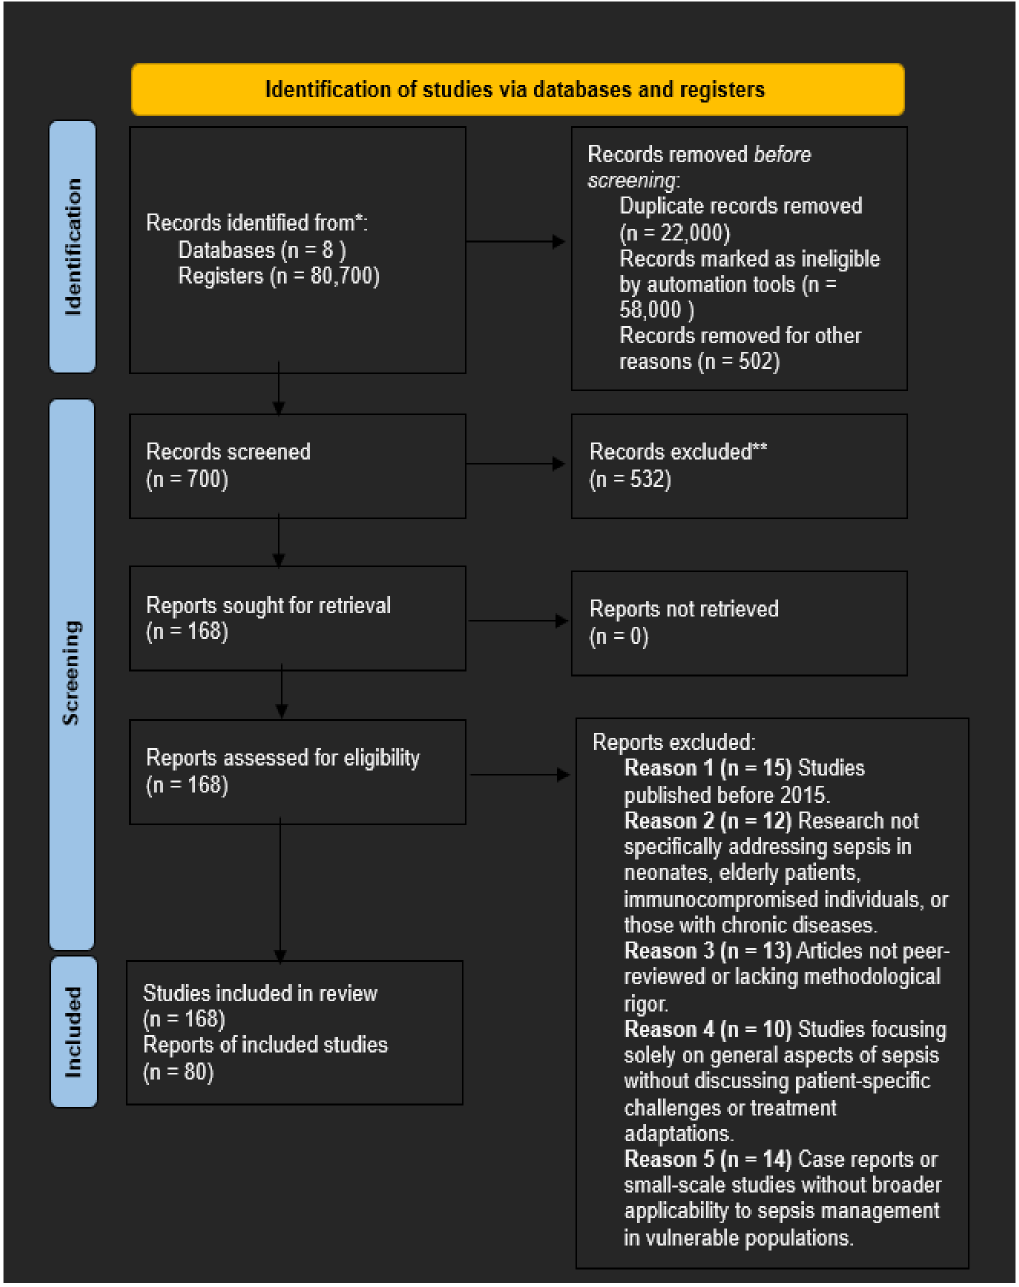
Following the removal of duplicate records (22,000) and studies excluded due to lack of relevance, incomplete data, or methodological limitations (502), a total of 700 articles remained for screening.

During the initial screening phase, 532 records were excluded based on predefined criteria, primarily for not specifically addressing sepsis in neonates, elderly individuals, immunocompromised patients, or those with chronic diseases. In the first review phase, 168 studies were assessed for eligibility, with articles evaluated for their relevance to sepsis pathophysiology, diagnostic tools, and treatment strategies.

In the second phase, a more detailed evaluation was conducted, applying stricter inclusion criteria related to immune dysregulation, microvascular dysfunction, and patient-specific therapeutic approaches. Studies that focused solely on general aspects of sepsis without addressing unique challenges faced by high-risk patient groups were excluded.

The final selection included 80 studies, covering a wide range of topics, including the pathophysiological mechanisms of sepsis, personalized treatment strategies, and emerging diagnostic technologies. These studies, published between 2015 and 2025, provide valuable insights into optimizing sepsis management in vulnerable populations.

Figure 1: PRISMA Flow Diagram of articles related to Microcirculatory Dysfunction and Sepsis Management in Vulnerable Patient Populations



Identification of studies via databases and registers
Identification
Screening
Included
Records identified from*:
Databases (n = 8)
Registers (n = 80,700)
Records removed *before screening*:
Duplicate records removed (n = 22,000)
Records marked as ineligible by automation tools (n = 58,000)
Records removed for other reasons (n = 502)
Records screened (n = 700)
Records excluded** (n = 532)
Reports sought for retrieval (n = 168)
Reports not retrieved (n = 0)
Reports assessed for eligibility (n = 168)
Reports excluded:
Studies included in review (n = 168)
Reports of included studies (n = 80)

Reason 1 (n = 15) Studies published before 2015.
Reason 2 (n = 12) Research not specifically addressing sepsis in neonates, elderly patients, immunocompromised individuals, or those with chronic diseases.
Reason 3 (n = 13) Articles not peer-reviewed or lacking methodological rigor.
Reason 4 (n = 10) Studies focusing solely on general aspects of sepsis without discussing patient-specific challenges or treatment adaptations.
Reason 5 (n = 14) Case reports or small-scale studies without broader applicability to sepsis management in vulnerable populations.

This systematic review was conducted following the PRISMA 2020 guidelines. The PRISMA checklist and flow diagram are provided as supplementary materials.

This methodology enabled a comprehensive analysis of the specialized literature, synthesizing key findings on microcirculatory dysfunction and sepsis management in vulnerable patient populations. By incorporating data from multiple disciplines, this approach provided a well-rounded understanding of sepsis pathophysiology, diagnostic innovations, and personalized treatment strategies.

The studies included in the results section strictly followed the predefined inclusion criteria, ensuring the selection of high-quality and relevant research aligned with the core objectives of this review. These studies were systematically analyzed and synthesized to explore the relationship between microvascular alterations, immune dysregulation, and patient-specific therapeutic approaches, offering objective data and clinically significant insights to enhance sepsis management in high-risk groups.

Sepsis in High-Risk Patient Populations: Unique Challenges and Management Strategies

Patients at increased risk of sepsis belong to special categories, each with specific physiological, immunological, and clinical characteristics that significantly influence disease progression and response to treatment. In these groups, sepsis can progress rapidly, present with atypical symptoms, and have a more severe prognosis, requiring personalized management and close monitoring (Table 1).

Table 1: Categories of Patients at Increased Risk of Sepsis and Their Specific Characteristics

Patient Category	Specific Characteristics	References
Elderly Patients	- Immunosenescence: weakened immune response - Blunted inflammatory response (atypical symptoms) - Compromised cardiovascular and renal function - Increased risk of multi-organ dysfunction	[59], [60]
Patients with Chronic Comorbidities	- Impaired immunity due to preexisting conditions (diabetes, kidney disease, COPD, heart failure) - Increased oxidative stress and chronic inflammation - Risk of hemodynamic imbalances and fluid overload	[61]
Pediatric Patients	- Immature immune system - Increased risk of bacteremia and multi-organ dysfunction - Different drug metabolism (requires careful dose adjustment) - Nonspecific symptoms (lethargy, hypothermia, feeding difficulties)	[62], [63]
Immunocompromised Patients	- Weakened inflammatory response (atypical symptoms) - Increased susceptibility to opportunistic infections - Requires aggressive antibiotic therapy and intensive monitoring	[64], [65]
Pregnant Women	- Physiological changes increase infection susceptibility and excessive inflammation - Early signs may be masked by cardiovascular adaptations - Specific risks: chorioamnionitis, postpartum endometritis - Therapy must be carefully selected to ensure fetal safety	[66], [67]

As we can see in Table 1, elderly patients face a range of physiological and immunological changes that increase their vulnerability to sepsis. With aging, the immune system undergoes immunosenescence, characterized by a weakened innate and adaptive immune response. This leads to a reduced ability to combat infections and a delayed activation of defense mechanisms [59]. Additionally, the inflammatory response may be blunted, meaning classic symptoms of sepsis, such as fever and tachycardia, may be absent or less pronounced. Cardiovascular and renal functions are often compromised in elderly individuals, making hemodynamic balance and fluid management more challenging. Their overall frailty, combined with a higher risk of multi-organ dysfunction, necessitates a carefully tailored therapeutic approach to prevent rapid deterioration and severe complications [60].

Patients with chronic comorbidities represent another high-risk group, as preexisting conditions directly impact infection response and the body's ability to maintain homeostasis during sepsis. Diabetes mellitus, for example, impairs immune function by increasing oxidative stress, altering neutrophil function, and reducing phagocytic capacity, making severe infections and associated complications more likely [61]. Chronic kidney disease leads to the accumulation of uremic toxins that suppress immune function and increase susceptibility to opportunistic infections. Additionally, patients with chronic obstructive pulmonary disease or heart failure exhibit persistent inflammatory states and limited functional reserves, causing sepsis to exacerbate these conditions rapidly. For these patients, treatment strategies must balance infection control, organ protection, and the prevention of adverse effects, such as fluid overload from aggressive resuscitation.

Pediatric patients exhibit significant physiological and immunological differences compared to adults, affecting both the presentation and management of sepsis. The immune system of neonates and infants is underdeveloped, resulting in a reduced ability to mount an effective response against infections, which increases the risk of bacteremia and multi-organ dysfunction [62]. Additionally, drug metabolism differs in children, requiring careful dose adjustments for antibiotics and other therapies based on body weight and organ maturity. Clinical signs of sepsis in this group are often non-specific, including lethargy, respiratory distress, hypothermia, or feeding difficulties, making early diagnosis challenging. Close monitoring and rapid intervention are crucial to preventing severe complications and reducing mortality in pediatric sepsis [63].

Immunocompromised patients, including those with cancer, autoimmune diseases, or those undergoing immunosuppressive therapy, are highly vulnerable to sepsis due to an impaired immune system that cannot effectively control infections. The absence of a robust inflammatory response allows infections to spread quickly, and classic sepsis symptoms such as fever and leukocytosis may be absent, leading to delayed diagnosis [64]. These patients are also prone to opportunistic infections caused by pathogens that are typically non-threatening to immunocompetent individuals, complicating the choice of antimicrobial therapy. Sepsis management in immunocompromised patients requires an aggressive approach, including the rapid administration of broad-spectrum antibi-otics, intensive monitoring, and, in some cases, adjunctive therapies to support immune function [65].

Pregnant women represent a unique high-risk category for sepsis, as physiological changes during pregnancy can increase both infection susceptibility and exaggerated inflammatory responses. The immune system undergoes adaptations to tolerate the presence of the fetus, potentially reducing the ability to fight off infections effectively [66]. Simultaneously, increased plasma volume and cardiac output alter the body's response to infection and can mask early signs of sepsis. Obstetric infections, such as chorioamnionitis and postpartum endometritis, are common causes of sepsis during pregnancy and can have severe consequences for both the mother and the fetus. Treating sepsis in pregnant women requires careful consideration of fetal safety, necessitating the selection of appropriate antibiotics and close hemodynamic monitoring to prevent maternal and fetal complications [67].

Each of these special patient categories requires a personalized approach to sepsis management, tailored to their unique physiological and immunological characteristics. Early diagnosis, intensive monitoring, and prompt therapeutic interventions are essential to improving outcomes and reducing mortality in these vulnerable populations.

Tailored Therapeutic Approaches for Special Patient Populations in Sepsis

Managing sepsis in high-risk patient populations requires a personalized therapeutic approach that considers age, comorbidities, immune status, and physiological differences. Standard treatment protocols may not be fully applicable to these groups, necessitating dose adjustments, targeted antimicrobial strategies, and specialized supportive interventions to optimize outcomes while minimizing complications.

Table 2 presents the key therapeutic considerations for each of these high-risk patient groups, highlighting the necessary adjustments in sepsis management to optimize clinical outcomes and reduce complications.

Table 2: Tailored Therapeutic Approaches for Special Patient Populations in Sepsis

Patient Category	Key Therapeutic Considerations	References
Elderly Patients	- Adjust antibiotic dosages due to reduced renal and hepatic function - Lower doses or extended intervals for renally excreted antibiotics (e.g., aminoglycosides, vancomycin) to prevent nephrotoxicity - Monitor for fluid overload and hypotension with advanced hemodynamic tools (e.g., echocardiography)	[68], [69], [72]
Pediatric Patients	- Use weight-based dosing due to immature liver enzymes and different drug metabolism - Close monitoring of oxygenation, perfusion, and fluid balance - Early noninvasive ventilation (e.g., high-flow nasal cannula) to prevent respiratory failure - Adjust antibiotic regimens based on age-specific pharmacokinetics	[73], [74]
Patients with Chronic Comorbidities	- Modify medication regimens to prevent interactions (e.g., fluid overload in heart failure) - Adjust diabetes management to avoid sepsis-induced hyperglycemia - Consider early renal replacement therapy in patients with kidney disease - Balance infection control with organ protection strategies	[71], [75]
Immunocompromised Patients	- Use prolonged or higher-dose antibiotic courses if needed, balancing toxicity risks - Consider antifungal and antiviral coverage for broader protection - Utilize immunotherapies such as G-CSF for neutropenic patients - Monitor for opportunistic infections and tailor treatment accordingly	[70], [76], [79], [80]
Pregnant Women	- Select antibiotics carefully to avoid teratogenic risks (prefer beta-lactams, macrolides, cephalosporins) - Adjust dosages based on increased plasma volume and altered metabolism - Monitor fetal well-being and placental perfusion in maternal hypotension - Involve obstetric and neonatal specialists for optimal maternal-fetal outcomes	[83], [84], [85], [86], [87]

According to Table 2, antibiotic and medication dosages must be carefully adapted based on age, underlying conditions, and overall patient status. In elderly patients, reduced renal and hepatic function can significantly alter drug metabolism and clearance, increasing the risk of toxicity [68]. Lower doses or extended dosing intervals may be required for renally excreted antibiotics such as aminoglycosides and vancomycin to prevent accumulation and nephrotoxicity [69]. Pediatric patients have immature liver enzyme systems and differing body compositions, necessitating weight-based dosing and close monitoring to ensure therapeutic efficacy while avoiding adverse effects. In immunocompromised individuals, higher or prolonged antibiotic courses may be required due to impaired immune clearance of pathogens, but this must be balanced against the risk of toxicity and resistance [70]. Patients with chronic diseases, such as diabetes or heart failure, may require modifications in medication regimens to avoid interactions or worsening of underlying conditions, such as fluid overload with aggressive intravenous hydration [71].

Supportive interventions play a critical role in managing sepsis in these vulnerable populations. Elderly patients often have diminished cardiovascular reserve, making them prone to hypotension and fluid overload, requiring careful hemodynamic monitoring using advanced tools such as echocardiography or dynamic fluid responsiveness tests [72]. Pediatric patients, particularly neonates, have immature cardiovascular and respiratory systems, necessitating closer monitoring of oxygenation, perfusion, and fluid balance [73]. In critically ill patients with underlying respiratory diseases such as chronic obstructive pulmonary disease or in neonates with underdeveloped lung function, early implementation of noninvasive ventilation or high-flow nasal cannula therapy can help prevent respiratory deterioration [74]. Patients with renal impairment may require early initiation of renal replacement therapy to prevent worsening metabolic derangements and fluid overload [75].

Targeted antimicrobial therapy is essential to optimizing treatment outcomes while minimizing the risk of antibiotic resistance, particularly in patients with recurrent sepsis [76]. Broad-spectrum antibiotics should be initiated promptly but de-escalated based on culture results and antimicrobial susceptibility testing to avoid unnecessary prolonged exposure to broad-spectrum agents [77]. In patients with frequent hospitalizations or prior antibiotic exposure, local resistance patterns should guide empirical therapy to ensure adequate pathogen coverage [78]. Immunocompromised patients, such as those undergoing chemotherapy or organ transplant recipients, are at higher risk for fungal or viral infections in addition to bacterial sepsis, necessitating a broader diagnostic approach and potential inclusion of antifungal or antiviral agents in their treatment regimen [79].

Immunotherapy has emerged as a potential adjunct in managing sepsis, particularly in immunocompromised individuals. Strategies such as the administration of granulocyte colony-stimulating factor (G-CSF) can enhance neutrophil function in patients with chemotherapy-induced neutropenia, reducing the risk of severe infections [80]. Intravenous immunoglobulins (IVIG) may be beneficial in certain septic patients with antibody deficiencies, such as those with primary immunodeficiencies or hypogammaglobulinemia secondary to chronic diseases [81]. Additionally, emerging therapies targeting immune modulation, such as checkpoint inhibitors and cytokine blockade, are being explored to balance excessive inflammatory responses and prevent immune paralysis in sepsis [82]. However, these approaches require further clinical validation to determine their efficacy and safety across different patient populations.

Special considerations are necessary when treating sepsis in pregnant women to minimize risks to both the mother and fetus. Physiological changes in pregnancy, including increased plasma volume, altered renal clearance, and changes in drug metabolism, require careful selection and dosing of medications [83]. Certain antibiotics, such as tetracyclines and fluoroquinolones, should be avoided due to potential teratogenic effects or adverse fetal outcomes [84]. Beta-lactams, macrolides, and selected cephalosporins are generally considered safe and are preferred when treating infections in pregnancy [85]. Management of sepsis in pregnant patients also involves close fetal monitoring, particularly in cases of maternal hypotension, as reduced placental perfusion can lead to fetal distress [86]. Early involvement of obstetric and neonatal specialists is crucial to ensuring optimal maternal and fetal outcomes, particularly in cases requiring preterm delivery due to worsening maternal condition [87].

A tailored therapeutic approach is essential in managing sepsis in high-risk populations, as a one-size-fits-all strategy may not be effective or safe. Personalized dosing regimens, targeted antimicrobial selection, intensive supportive care, and emerging immunomodulatory therapies must be carefully integrated into treatment plans to improve survival and reduce complications in these vulnerable patient groups.

Outcomes and Prognostic Factors in Sepsis Among High-Risk Patient Populations

The prognosis of sepsis varies significantly among different patient populations, with special categories such as the elderly, pediatric patients, immunocompromised individuals, those with chronic diseases, and pregnant women facing distinct challenges that influence survival rates, recurrence risk, and long-term health outcomes. The interaction between individual patient characteristics, severity of illness, and therapeutic interventions plays a crucial role in determining overall outcomes.

Mortality and morbidity rates in sepsis differ across patient groups, with elderly individuals exhibiting the highest case fatality rates due to pre-existing frailty, immune senescence, and a diminished physiological reserve. Studies indicate that sepsis-related mortality in elderly patients can exceed 40%, particularly in those with multi-organ dysfunction or underlying cardiovascular disease [88]. Pediatric patients generally have lower mortality rates due to their greater physiological resilience and the ability to recover from severe infections when treated promptly [89]. However, neonates and premature infants remain highly vulnerable, with significantly higher sepsis-related mortality due to their immature immune systems and increased susceptibility to bloodstream infections [90]. Immunocompromised individuals, including cancer patients, transplant recipients, and those undergoing immunosuppressive therapy, also face elevated mortality risks, as their inability to mount an adequate immune response allows infections to progress more aggressively [91]. Patients with chronic diseases such as diabetes, chronic kidney disease, and chronic obstructive pulmonary disease experience worse outcomes due to baseline organ dysfunction, which limits their ability to compensate for sepsis-induced metabolic and inflammatory disturbances [92]. Pregnant women with sepsis generally have lower mortality rates compared to other high-risk groups, but severe maternal sepsis remains a leading cause of maternal morbidity and can result in adverse fetal outcomes, including preterm birth and stillbirth [93].

The success of treatment and the likelihood of sepsis recurrence depend on multiple factors, including early diagnosis, appropriate antimicrobial therapy, hemodynamic stabilization, and organ support. Patients in high-risk categories often require more aggressive and prolonged interventions, yet they may also experience higher rates of treatment failure. In elderly patients, delayed recognition of sepsis due to atypical presentations contributes to increased mortality, and even those who survive the acute phase frequently develop post-sepsis complications such as cognitive decline and functional impairment [94]. Pediatric patients, despite their potential for recovery, may experience long-term immunological and developmental consequences following severe sepsis. Immunocompromised individuals often require extended antimicrobial treatment due to persistent infection risks, but this increases their susceptibility to antimicrobial resistance and recurrent sepsis episodes [95]. Patients with chronic diseases frequently experience sepsis relapses, particularly when their underlying conditions are poorly controlled, leading to recurrent hospitalizations and a progressive decline in overall health status [96].

Prognostic factors vary based on patient category and the therapeutic approach used. In elderly patients, markers of frailty, pre-existing comorbidities, and the presence of multi-organ dysfunction strongly predict poor outcomes. In pediatric sepsis, factors such as gestational age, birth weight, and early initiation of antibiotics influence survival rates [97]. Immunocompromised patients with profound neutropenia or severe lymphopenia are at the highest risk of mortality, particularly when infections are caused by multidrug-resistant organisms or opportunistic pathogens [98]. The effectiveness of immunotherapy, such as granulocyte colony-stimulating factor (G-CSF) or intravenous immunoglobulin (IVIG), in improving survival in these patients remains an area of ongoing research. In patients with chronic diseases, glycemic control in diabetics, renal function stability in those with kidney disease, and optimal management of pulmonary disease play critical roles in determining outcomes [99]. Pregnant women with sepsis have better prognoses when infections are detected early and treated promptly, but complications such as septic shock, disseminated intravascular coagulation, and fetal distress significantly worsen both maternal and fetal outcomes [100,101].

The long-term impact of sepsis on quality of life has become an increasingly important topic of discussion, particularly with the recognition of post-sepsis syndrome (PSS), a condition characterized by persistent physical, cognitive, and psychological impairments following recovery from sepsis [102]. Many sepsis survivors experience chronic fatigue, muscle weakness, neuropathy, and reduced exercise tolerance, which significantly impact their ability to perform daily activities [103]. Cognitive dysfunction, including memory impairment and difficulty concentrating, is particularly common in elderly patients and those who require prolonged intensive care unit (ICU) stays [104]. Anxiety, depression, and post-traumatic stress disorder (PTSD) are frequently reported, further diminishing quality of life [105]. Pediatric patients who survive sepsis may experience developmental delays and long-term neurocognitive impairments, especially if they suffered from hypoxia or severe inflammation during the acute phase [106]. Immunocompromised patients often face ongoing infection risks and require long-term prophylactic antimicrobial therapy, increasing their burden of care. Individuals with chronic diseases who survive sepsis often experience accelerated disease progression, leading to increased dependence on healthcare resources [107]. Pregnant women who recover from sepsis may face complications such as placental insufficiency, preterm labor, or long-term cardiovascular effects, emphasizing the need for close postpartum monitoring [108].

The impact of long-term sepsis management on patient health and functionality underscores the importance of comprehensive post-discharge care. Early rehabilitation programs, including physical therapy and cognitive training, can help mitigate some of the adverse effects of post-sepsis syndrome [109]. Ongoing monitoring for secondary infections, organ dysfunction, and psychological distress is essential to improving the long-term well-being of sepsis survivors. Targeted interventions, such as personalized nutrition plans, immune-modulating therapies, and infection prevention strategies, may help reduce the risk of recurrent sepsis and promote a better quality of life for high-risk patients [110].

The prognosis and long-term outcomes of sepsis vary widely depending on patient characteristics, timely intervention, and post-sepsis care. While advances in early recognition and targeted therapies have improved survival rates, the high burden of post-sepsis complications highlights the need for continued research and multidisciplinary approaches to optimize long-term recovery in vulnerable populations.

Microcirculatory Dysfunction in Sepsis and Its Clinical Implications

Microcirculatory dysfunction plays a critical role in the progression and severity of sepsis, significantly influencing patient outcomes. Various diagnostic techniques are employed to assess alterations in microvascular perfusion, endothelial integrity, and oxygen delivery at the tissue level. Sublingual video microscopy, using techniques such as sidestream dark field (SDF) imaging, allows for direct visualization of capillary flow abnormalities [111]. Near-infrared spectroscopy (NIRS) is utilized to evaluate tissue oxygenation, while biomarkers such as lactate levels and endothelial activation markers provide additional insights into microvascular impairment [112].

The characteristics of microcirculatory dysfunction in sepsis differ significantly from those observed in other critical illnesses. Septic patients frequently exhibit extensive capillary heterogeneity, increased leukocyte-endothelial interactions, and impaired oxygen extraction, even when macrocirculatory parameters such as blood pressure appear normal [113]. Comparing microvascular alterations between septic and non-septic critically ill patients helps elucidate underlying pathophysiological mechanisms and guides the development of targeted interventions [114].

Table 3 summarizes key diagnostic techniques used to assess microcirculatory dysfunction in sepsis, highlighting their advantages, limitations, and clinical relevance in managing critically ill patients.

Table 3: Diagnostic Analysis of Microcirculatory Dysfunction in Sepsis

Category	Aspect Analyzed	Description	Advantages	Disadvantages	Examples	References
Diagnostic Techniques Used	Sublingual Video Microscopy (SDF/OPS Imaging)	Direct visualization of microvascular flow abnormalities and capillary perfusion deficits.	Real-time, bedside assessment of microcirculation.	Operator-dependent, limited standardization.	Identification of capillary heterogeneity and sluggish flow in sepsis.	[115], [116]
	Near-Infrared Spectroscopy (NIRS)	Measures tissue oxygenation to assess microvascular dysfunction in real-time.	Non-invasive, continuous monitoring.	Limited spatial resolution, indirect measurement.	Detects impaired tissue oxygen extraction in septic shock.	[117], [118]
	Plasma Biomarkers (Lactate, Endothelial Activation Markers)	Biochemical markers reflecting endothelial dysfunction and microvascular impairment.	Easily accessible, quantitative assessment.	Nonspecific, affected by multiple factors.	Elevated lactate and angiopoietin-2 levels indicating sepsis severity.	[119], [120]
Key Microcirculatory Features	Capillary Perfusion Deficits	Impaired blood flow distribution at the microvascular level, leading to tissue hypoxia.	Helps explain oxygen delivery failure in sepsis.	Difficult to correct solely with macrocirculatory support.	Decreased proportion of perfused capillaries in septic patients.	[121], [122]
	Endothelial Dysfunction and Glycocalyx Damage	Disruption of endothelial barrier function, increasing vascular permeability, and inflammation.	Critical factor in sepsis progression and organ failure.	No direct bedside measurement is currently available.	Degradation of the endothelial glycocalyx leading to capillary leakage.	[123], [124]
	Oxygen Extraction and Mitochondrial Dysfunction	Sepsis-induced alterations in cellular oxygen utilization and mitochondrial energy production.	Key insight into metabolic failure in septic shock.	Challenging to measure in clinical settings.	Reduced oxygen consumption despite adequate oxygen delivery.	[125], [126]

According to Table 3, the assessment of microcirculatory dysfunction in sepsis highlights the necessity of a multimodal approach for accurate diagnosis and patient management. Sublingual video microscopy remains a valuable bedside tool for directly visualizing microvascular perfusion abnormalities [115,116], while near-infrared spectroscopy provides non-invasive, real-time insights into tissue oxygenation deficits [117,118]. Biomarkers such as lactate and endothelial activation markers offer an accessible means of assessing microvascular impairment [119,120], though they lack specificity and require correlation with other clinical parameters.

The distinct microcirculatory alterations observed in sepsis, including capillary perfusion deficits [121,122], endothelial dysfunction [123,124], and mitochondrial impairment [125,126], underscore significant pathophysiological differences compared to other critical illnesses. These findings suggest that conventional macrocirculatory-focused management strategies may be insufficient, emphasizing the need for personalized interventions targeting microvascular restoration.

Integrating microcirculatory assessment with inflammatory and metabolic biomarkers can enhance early risk stratification, optimize therapeutic strategies, and improve patient outcomes. This underscores the importance of a multidisciplinary approach, incorporating intensivists, infectious disease specialists, and hemodynamic monitoring experts to refine sepsis management and reduce mortality in high-risk populations.

Challenges

The treatment of sepsis in high-risk patient populations presents significant clinical and scientific challenges. Despite advancements in early diagnosis, antimicrobial therapies, and supportive care, difficulties persist in tailoring treatment strategies to meet the unique needs of vulnerable groups. Two major challenges are the identification of reliable prognostic markers to predict disease progression and the absence of standardized protocols for the personalized management of sepsis in special populations [127].

A primary obstacle in managing sepsis in these high-risk groups is the lack of robust prognostic markers that enable early risk stratification and guide treatment decisions. In the general sepsis population, biomarkers such as procalcitonin, C-reactive protein, and lactate levels are commonly used to assess disease severity and response to treatment [128]. However, in elderly patients, these markers may be less reliable due to an altered inflammatory response and atypical sepsis presentation. Similarly, in immunocompromised patients, the absence of a strong inflammatory response can lead to falsely low biomarker levels, delaying diagnosis and appropriate intervention [129]. Pediatric patients, especially neonates, have distinct immune responses that differ from adults, making it difficult to apply standard sepsis biomarkers to this population [130]. Recent studies have explored cytokines such as IL-6 and IL-10 as potential markers for sepsis severity in immunocompromised and pediatric patients, but further research is needed to validate their clinical utility. The absence of well-defined biomarkers complicates early detection, treatment optimization, and outcome prediction in these vulnerable groups [131].

Another key challenge is the lack of standardized protocols for the individualized management of sepsis in special populations. Although general sepsis guidelines exist, they do not always account for the unique physiological and immunological characteristics of elderly patients, pediatric patients, those with chronic diseases, or immunocompromised individuals [132]. For instance, fluid resuscitation strategies must be carefully adjusted in elderly patients with reduced cardiac and renal function to prevent fluid overload. Pediatric patients require weight-based adjustments for antibiotics and vasoactive medications, but there is no universal protocol guiding optimal dosing in neonates with sepsis [133]. Immunocompromised patients often require broader anti-microbial coverage, yet prolonged exposure to broad-spectrum antibiotics increases the risk of resistance and secondary infections, making antimicrobial stewardship particularly complex [134]. Similarly, in pregnant women, balancing maternal treatment with fetal safety is a significant challenge, as some life-saving antimicrobial and vasopressor therapies pose potential risks to fetal development. The absence of tailored sepsis management guidelines for these groups leads to variability in clinical practice and inconsistencies in patient outcomes [135].

Standardizing diagnostic and treatment protocols is essential for improving sepsis management in high-risk populations. Without clear evaluation and treatment criteria, clinical decision-making often relies on physician experience rather than evidence-based guidelines, leading to disparities in care across healthcare settings [136].

DISCUSSION

The findings from this analysis highlight the complexity of managing sepsis in high-risk patient populations and underscore the need for a personalized, multidisciplinary approach. The strength of evidence supporting various therapeutic interventions, prognostic indicators, and post-sepsis outcomes varies across patient groups, influencing decision-making for healthcare providers, researchers, and policy-makers.

Early and targeted antimicrobial therapy remains the cornerstone of sepsis treatment, with strong evidence (Level A) supporting its role in improving survival rates. The literature consistently emphasizes the importance of initiating broad-spectrum antibiotics within the first hour of suspected sepsis to reduce mortality, particularly in immunocompromised patients and neonates who are highly susceptible to rapid disease progression [137]. However, antibiotic stewardship remains a critical concern, as prolonged or inappropriate antimicrobial use contributes to resistance, especially in patients with recurrent sepsis [138].

Supportive interventions such as hemodynamic monitoring and organ support therapies play a crucial role in managing sepsis in elderly patients, pediatric populations, and those with chronic comorbidities [139]. Evidence suggests that goal-directed fluid re-suscitation and vasopressor therapy improve outcomes in patients with sepsis-induced hypotension (Level A). However, the literature also indicates that fluid overload can worsen prognosis, particularly in elderly patients with cardiac or renal impairment, necessitating individualized resuscitation strategies [140]. Pediatric patients require weight-based hemodynamic adjustments, yet a lack of standardized protocols for fluid management in neonatal sepsis creates challenges in optimizing treatment [141].

The role of immunotherapy in sepsis treatment remains an evolving area of research, with emerging evidence suggesting potential benefits for immunocompromised patients. Studies exploring the use of intravenous immunoglobulins (IVIG) and cytokine-targeting therapies indicate possible improvements in immune function and infection control (Level B) [142]. However, data remain inconclusive, and the heterogeneity of immune responses in different patient groups complicates the identification of optimal candidates for such therapies [143].

Post-sepsis outcomes and long-term patient recovery have become increasingly recognized as critical aspects of sepsis care, particularly with the identification of post-sepsis syndrome (PSS) [144]. Studies show that sepsis survivors, particularly elderly patients and those with pre-existing comorbidities, frequently experience persistent physical, cognitive, and psychological impairments that reduce their quality of life (Level A) [145]. The literature highlights the need for early rehabilitation programs, including physical therapy and mental health support, to improve post-sepsis functional outcomes [146]. Pediatric patients, though generally more resilient, may experience long-term developmental delays, while immunocompromised individuals remain at high risk for recurrent infections [147].

The analysis of sepsis treatment and outcomes in high-risk populations underscores the need for a more personalized approach to management. While early antimicrobial therapy, hemodynamic support, and organ protection strategies are well established, optimizing treatment for specific patient groups remains a challenge [148,149]. Further research into immunomodulatory therapies, targeted resuscitation strategies, and post-sepsis rehabilitation programs could improve outcomes for vulnerable populations. For healthcare systems and policy-makers, prioritizing research funding and developing population-specific guidelines will be crucial in advancing sepsis care.

CONCLUSION

The findings of this analysis reinforce and expand upon the existing research on sepsis management in high-risk patient populations, emphasizing the distinct pathophysiological mechanisms and therapeutic challenges that differentiate these groups from the general sepsis population. The evidence strongly supports the fundamental role of age-related immune changes, comorbid conditions, and immune suppression in altering sepsis progression, response to treatment, and long-term recovery. These differences explain the variability in treatment outcomes and underscore the necessity for patient-specific, tailored therapeutic approaches.

From an antimicrobial therapy perspective, the literature confirms that early and targeted antibiotic administration remains the cornerstone of sepsis treatment, particularly in immunocompromised patients and neonates, where delayed intervention significantly worsens prognosis. However, the growing concern of antimicrobial resistance in patients with recurrent sepsis highlights the urgent need for enhanced antimicrobial stewardship programs and the integration of rapid molecular diagnostics to optimize therapy selection. The challenge of balancing broad-spectrum coverage with the risk of resistance remains a key consideration in long-term sepsis management.

The role of hemodynamic support and organ protection strategies in sepsis treatment is well established, with evidence favoring individualized fluid resuscitation and vaso-pressor therapy based on patient-specific factors such as age, renal function, and baseline cardiovascular status. While goal-directed resuscitation strategies improve survival, the risk of fluid overload in elderly and chronically ill patients necessitates a more precise, dynamic approach to fluid management. The increasing use of bedside ultrasonography and advanced monitoring techniques presents an opportunity to refine resuscitation protocols and improve patient outcomes.

The growing recognition of post-sepsis syndrome (PSS) highlights the need for a more comprehensive approach to sepsis care, extending beyond the acute phase to address long-term health complications. Studies confirm that sepsis survivors, particularly elderly individuals and those with preexisting conditions, frequently experience persistent physical, cognitive, and psychological impairments that significantly impact their quality of life. Post-sepsis rehabilitation programs, including structured physical therapy, cognitive assessments, and mental health support, are increasingly recognized as essential components of recovery. However, gaps remain in the availability and accessibility of these services, underscoring the need for healthcare systems to prioritize long-term sepsis care.

These findings highlight the importance of integrating personalized therapeutic strategies, advanced diagnostic technologies, and long-term rehabilitation programs into sepsis management.

Implications for Future Research

Given the limitations of standard sepsis management in high-risk populations, future research should focus on developing personalized treatment strategies that account for immune dysfunction, comorbid conditions, and age-related physiological changes. Studies investigating immunomodulatory therapies, such as IL-6 and IL-10 inhibitors, could provide new therapeutic avenues for immunocompromised patients who fail to mount an adequate immune response. Additionally, research into host-directed therapies, including immune checkpoint inhibitors and cell-based treatments, may help restore immune balance in patients with immune exhaustion or dysregulated inflammatory responses.

The growing threat of antimicrobial resistance, particularly in patients with recurrent sepsis, underscores the need for novel antibiotic stewardship strategies. Future studies should explore rapid molecular diagnostics and point-of-care pathogen identification tools to facilitate early, targeted antibiotic therapy while minimizing unnecessary broad-spectrum antibiotic use. Additionally, research into alternative antimicrobial approaches, such as bacteriophage therapy and antimicrobial peptides, could provide effective solutions for multidrug-resistant infections. The development of nanotechnology-based drug delivery systems to enhance antibiotic penetration into infected tissues and biofilms should also be a priority.

Hemodynamic monitoring and resuscitation strategies in sepsis require further refinement to improve outcomes in specific patient populations. Research into precision-guided fluid resuscitation, incorporating real-time hemodynamic assessment tools such as microcirculatory imaging and noninvasive cardiac output monitoring, could help tailor fluid therapy and prevent complications such as fluid overload in elderly and chronically ill patients. Additionally, studies comparing restrictive versus liberal fluid strategies in different patient populations could provide insights into optimizing volume resuscitation while minimizing adverse effects.

The long-term impact of sepsis, particularly post-sepsis syndrome (PSS), remains an area requiring further exploration. Future research should focus on identifying bi-omarkers that predict long-term cognitive, physical, and psychological impairments following sepsis. Large-scale longitudinal studies evaluating the effectiveness of rehabilitation programs, including physical therapy, neurocognitive interventions, and mental health support, are needed to establish standardized post-sepsis care protocols. Investigating the role of gut microbiome alterations in post-sepsis recovery may also provide opportunities for microbiome-targeted therapies to improve immune homeostasis and overall health outcomes.

Conflicts of interest and sources of funding

The authors declare no conflict of interest. No artificial intelligence automatically generated text was inserted in this manuscript, and no image was previously published in another journal or is under consideration for publication elsewhere. This research received no external funding.

The risk of bioterrorist and biocrime attack in the contemporary world

Ioana A. Gal[1], Teodora B. Eremia[1], Mihail S. Tudosie[1,2], Viorel Ordeanu[1,3,4]

Abstract: *The biological attack is the artificial spread by various means of pathogens that can cause serious infectious and contagious diseases as well as the spread of germ toxins that can be used by an aggressor as a means of fighting in order to reduce the troops' fighting force, by causing serious disease outbreaks or by killing people, animals and/or plants.*

Biological agents are microorganisms and/or microbial, animal or plant toxins, used as specific ammunition for biological weapons or used by terrorists in "bio-chem" attacks.

The risks of bioterrorism and biocrime attack in the contemporary world are real, and the history of the 20th century and the beginning of the 21st century confirms this.

It is necessary for preventive measures to be implemented on the unlawful use of biological agents. Early medical and non-medical countermeasures must be prepared for the prophylaxis, treatment and cessation of the consequences of any biological attack.

Keywords: *biological attack, bioterrorism, biocrime, medical protection*

INTRODUCTION

The biological attack is the artificial spread by various means of pathogens that can cause serious infectious and contagious diseases as well as the spread of germ toxins that can be used by an aggressor as a means of fighting in order to reduce the troops' fighting force, by causing serious disease outbreaks or by killing people, animals and/or plants.

Biological agents are microorganisms and/or microbial, animal or plant toxins, used as specific ammunition for biological weapons or used by terrorists in "bio-chem" attacks.

Terrorism, according to the League of Nations (1937), can be defined as the totality of criminal acts directed against a state or made or planned in order to create a state of terror in the minds of certain individuals, a group of people or the general public.

The objectives of terrorism can be grouped as follows:
a) Achieving political goals.

b) Attracting the attention of domestic and international public opinion to the "noble goal" pursued.

c) Undermining the authority of political regimes in some countries by creating a state of inner strain, insecurity and uncertainty, economic and social chaos.

d) Forcing authorities to meet certain requests.

g) Revenge on some officials.

h) Achieving military goals: management disruption at a strategic or operational level, diminishing or partially destroying the opponent's military potential, the disruption of the logistics system, paralyzing communications and telecommunication systems.

i) Religious fanaticism.

Bioterrorism consists in using or threatening to use the weapon of mass destruction for claims, with the declared intent of affecting the public health and/or the environment.

Currently, the following means are known for dispersing biological agents:
- Using saboteurs;
- Using vectors of microorganisms such as insects, mites, rodents or other infected animals;
- Incorporation of biological agents into explosive ammunition;
- Aerosolization – through aerosols released from the ground, air or sea – is considered the most effective means of contaminating large areas of territory within the shortest feasible time interval.

With regard to the production of biological weapons, both ordinary and resistant biological agents can be used, the latter being preferred, because they cause a form of the disease that can not be treated with the usual drugs, causing a disease outbreak of greater magnitude and severity.

In general, biological attacks are masked by natural epidemics, epizooties and epiphytosis, the latter two being generally considered to be economic attacks, with the aim of decreasing trade, implicitly, causing the decline of the standard of living in the affected area.

Biological attacks can also be manifested in the form of zooanthroponoses, affecting both animals and humans alike. [1, 2].

BRIEF HISTORY

"Read the history and, thus, discover what will be" Nicolae Iorga rightly said. The first "chemical weapons" - "toxic smoke" were used around 424 BC in the Peloponnesian War. The first users of the "biological weapon" (around 400 BC) can be considered the Scythians, who used arrows soaked in decomposing bodies or mixed with manure. The Spartans used to cast sieves of sulfur-moistened wood on sieged fortresses. Greek, Persian, and Roman literatures describe how dead animals were used for fountain-contaminate.

The Mongols, in the siege of the Kaffa fortress in Crimea, during the war waged between 1346 and 1347, used the corpses of those killed by the plague in order to infect or create a breach among the fortress defenders.

In the fifteenth century, the Spanish infested the French wine with blood from those infected with the pests. Also, at that time, Pizzaro distributed to the Americans in South America garments contaminated with smallpox. In the sixteenth century, the same virus was used by the English to impregnate the blankets distributed to the ameridian tribes that helped the French. In the war against Sweden in 1710, the Russian troops used the same method as the Tartar army did 400 years prior – namely, the use of the corpses of those killed by the plague.

During the Vietnam War, Americans used defoliant, desiccant and sterilizing herbicides. These substances did not fall under the Geneva Protocol of 1925 nor in the Convention on the Prohibition of Chemical Weapons. In the 1970s, ricin was used to assassinate Bulgarian dissidents Gheorghe Markov and Vladimir Kostov.

In 1976, the mayors of several US cities were the recipients of letters that were delivered in envelopes on which had been used an adhesive impregnated with lethal germs.

In 1979, among people working in a military microbiology unit, was recorded an epidemic of lung anthrax, resulting in over 60 deaths.

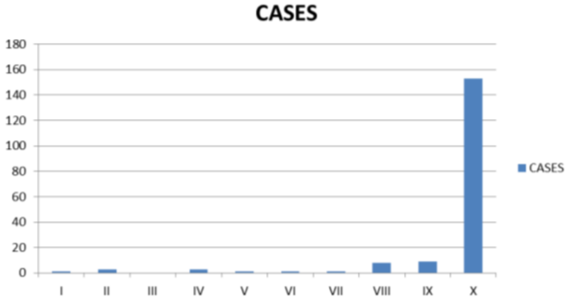
In 1984, in the US, members of the Bhagwan Shree Rajneesh sect have contaminated the food in Oregon restaurants with Salmonella Tiphi, causing 750 cases of major disease outbreaks.

In 1988, Iraq was spreading toxic and biological substances in Halabja, causing victims among the civilian population, predominantly children and women. Also in 1995, Iraq admitted to having in its posession Bacillus anthracis, botulinum toxin and aflatoxins, declaring to be ready to use them. All this demonstrates that, although the Convention on the Prohibition of Chemical Weapons was signed in 1972, the biological weapons research continued.

Since the end of 1992, there have been many more complex epidemics in the US, Milwaukee area, with wide-ranging effects: 400,000 cases of crypto-sporidium outbreaks from water consumption; in the spring of 1993, a respiratory epidemic with unidentified causes; during the fall of 1994, 250,000 cases of salmonella food poisoning.

On October 5th, 2001, in the US, Florida area, after having inhaled the anthrax bacillus, a tabloid's editor passed away. On October 20th, 2001, three letters containing anthrax spores were delivered to Washington DC, USA, having been received by Tom Daschle, a member of the Senate, and by Tom Brokaw from NBC News, as well as by the newspaper "The New York Post ". On November 2nd, 2001, a letter containing anthrax spores was found in Karachi, Pakistan, which was addressed to the newspaper "Daily Jang". In Santiago, a similar postal mailing resulted in disease outbreaks of thirteen people.

Figure 1. Frequency of the illicit use of biological agents in the 20th century, on decades (W. S. Carus) [α]



After September 11, 2001, the danger of massive terrorist attacks on the population of any part of the world is no longer just a working hypothesis. Chemical, biological or nuclear terrorism is, at present, one of the most serious threats to all states. Given the trend of interethnic and religious violence, as well as the number of cases of human rights violations in certain "high-risk" areas around the globe, analysts have warned against accentuating the risk of using these types of weapons in terrorist actions, underlining the imperative nature of urgently establishing non-proliferation measures.

TOTAL		168 cases

COUNTERMEASURES

Combating bioterrorist attacks involves, first of all, the intervention of the secret services, the police and the judicial system. Also, the intervention of the National Health System, the National Defense System, local communities and non-governmental organizations is crucial in the fight against these attacks. These non-medical contermeasures have an active, prophylactic role, preparing the population in the event of an attack. [3, 4, 5]

The responsibility for coordinating actions in these situations lies with the government of the country holding the EU Presidency, with the government of the country under attack and/or with the European Center for Infectious Disease Control.

The specific capabilities of the Medical Department of the Ministry of Defense are important for the medical protection against weapons of mass destruction and, in particular, for the fight against biological attacks. The Center for Military Medical Scientific Research has a Laboratory of Anti-infective Medical Protection and Epidemiological Emergencies, which functions as a specialized medical protection unit against biological weapons. It conducts military medical scientific research to protect troops and the civilian population against biological weapons and/or toxins, for biological warfare, bioterrorist attacks, or biological accidents.

Purpose		Cases	Deaths
1	Bioterrorism	751	0
2	Biocrime	130	10
TOTAL		881	10

Source: Carus W. S. „Bioterrorism and Biocrimes. The illicit use of biological agents since 1990", Center for Counterproliferation Research, National Defense University, Washington DC, 2001. [6]

If we make a retrospective of the 20th century, the most warrior of all, it is noticed that the practical use of weapons/biological agents was a reality. [6]

It is noted that in the last decade of the 20th century there were more cases than in the rest of the century.

OBSERVATION

An important component in the fight against biological attacks is represented by medical espionage, a constantly updated data base of new agents and existing diseases, thus, becoming the key to finding the most effective treatment.

With regard to the measures required for the imminence of a biological attack, individual protection means are used such as the gas mask - which is not 100% effective, but it decreases the amount of inhaled substance, having a protective role, because for most substances in order for harmfull effects to hapen it is necessary for large quantities to be inhaled.

Chemotherapics present much wider benefits in regards to the protection against biological weapons, acting switftly, having a broad spectrum and being easily administered in large communities.

Also, a very impressive step after a biological attack is the decontamination by appropriate physical and chemical means for the equipment, rooms, clothes, water sources, soil, etc. [7, 8, 9, 10]

CONCLUSIONS

The risks of bioterrorism and biocrime attacks in the contemporary world are real, and the history of the 20th century and the beginning of the 21st century confirms this. It is necessary to implement preventive measures on the unlawful use of biological agents. Early medical and non-medical countermeasures must be prepared for the prophylaxis, treatment and cessation of the consequences of any biological attack.

Abstract: Liver pathology represents, nowadays, a major cause of mortality and morbidity worldwide. Since MRI helps in limited cases in the differential diagnosis of various pathologies concerning liver tumors, other modern diagnostic strategies should be prioritized. Besides various tumoral biomarkers, contrast-enhanced ultrasound (CEUS) plays a substantial role in differentiating various liver pathologies due to its availability and specificity. Various contrast-enhanced substances used for CEUS assist mainly in detecting focal liver lesions and differentiating their malignant character. This review focuses on the main indications and limits of this novel investigation, considering that patients presenting with various liver pathologies are more challenging. We highlighted in our review the similarities with the CT/MRI imaging methods in reference to the specificity and sensitivity of the method, in its potential ability to detect various liver tumors. Moreover, the contrast agents used by CEUS are eliminated throughout the lungs, showing no evidence of hepatotoxic, nephrotoxic, or cardiotoxic events. In conclusion, the accessibility and safety of the procedure and the absence of the use of ionizing radiation point out that CEUS could be a stand-alone technique in the diagnosis and evaluation of complex liver pathologies.

Keywords: contrast-enhanced ultrasound; hepatocellular carcinoma; viral hepatitis; liver cirrhosis

INTRODUCTION

The diagnosis of various liver tumors remains, nowadays, challenging even if new diagnostic and prognostic tools are continuously developed [1–5]. In this context, contrast-enhanced ultrasound (CEUS) has been a widely used imaging method in Europe and Asia for over 10 years. CEUS consists of an ultrasound that employs contrast agents for increasing the accuracy of the investigation, typically injected intravenously. It can be compared with other contrast-enhanced imaging methods, such as CT or MRI, and it possesses the advantage of a real-time assessment of different focal liver lesions, improving their detection and characterization [1,2]. CEUS has become more popular in recent years than CT or MRI due to the fact that it has almost no adverse reactions, does not make use of any type of ionizing radiation, and can be employed successfully in patients with impaired renal function [1].

CEUS uses a special type of contrast agent that consists of a microsphere with an albumin, phospholipid, or surfactant-based shell and a gas filling, which subsequently forms a microbubble [2]. These microbubbles do not usually surpass 7 µm in size and have a mean diameter of 2.5 µm. These small sizes allow the microbubbles to freely circulate in the capillaries and impede them from passing through the vascular endothelium into the interstitial space, thus rendering them exclusively intravascular [2,6,7].

The microbubbles are excreted in two different ways depending on their components – the shell is metabolized in the liver, while the gas filling is eliminated through the lungs in about 10 to 15 minutes, even in patients with chronic obstructive pulmonary disease. This characteristic allows the utilization of these contrast agents in patients with renal failure, thus posing no risk of nephrotoxicity, when other contrast-enhanced methods such as CT or MRI are not indicated [2,6,8,9].

There are many contrast agents available around the world, but the most conventional are the sulfur hexafluoride microbubbles (SonoVue, Bracco), the perflutren lipid microspheres (Definity, Luminity), and the perfluorobutane microbubbles (Sonazoid).

SonoVue is the contrast agent most often used in Western countries and comprises a phospholipid shell that surrounds the sulfur hexafluoride microbubbles, resulting in a diameter of 2.5 µm. The agent is usually injected as a bolus of 2.4 mL in a peripheral vein (the antecubital vein), together with a 5 mL to 10 mL saline solution, using a large enough needle (more than 20-gauge) to ensure that the bubbles do not rupture during the procedure [1,2,6].

Sonazoid is mainly employed in Japan, Norway, and South Korea, and uses perfluorobutane microbubbles. Although it is similar to the other contrast agents used in CEUS, unlike those, Sonazoid can be phagocytized by the Kupffer cells and allows an additional evaluation of the liver in the Kupffer phase or the post-vascular phase. The agent can persist up to several hours in the liver and spleen after its vascular phase [1,6].

INDICATIONS - GENERAL CONTEXT

Even though the most common clinical application of CEUS is the characterization of focal liver lesions and differentiating between malignant and benign masses, there are studies and guidelines that show there are numerous other uses for this technique. As an intravascular contrast-agent imaging method, CEUS can provide information about different vascular diseases that may affect the carotid arteries or the aorta and other abdominal blood vessels, or it can help assess the thrombosis of the portal vein [10,11].

CEUS plays an important role in the imaging of the extravascular structures, mainly cavities, either physiological, such as the peritoneal, pleural cavities, biliary and gastrointestinal tracts, or non-physiological, including cysts, abscesses, or diverticula [12,13]. Thus, CEUS is used in gynecology to evaluate the uterus and the fallopian tubes, in nephrology and urology to help diagnose ureteral reflux and to discern between bladder or renal tumors and cysts or testicular masses. Excluding the liver evaluation, CEUS also has other applications in the assessment of the gastrointestinal tract.

It is successfully used in patients with inflammatory bowel diseases to estimate disease activity or with fistulae and abscesses, and at the same time, it can be administered orally in order to examine the bowel lumen [12–14].

CEUS can be successfully used for assessing different focal liver lesions seen on standard ultrasound and is indicated for the following: hepatic nodules larger than 10 mm (for nodules smaller than 10 mm CEUS can be attempted by an expert examiner); LI-RADS-graded liver lesions as LR-3, LR-4 or LR-M on CT or MRI: monitoring enhancement pattern changes over time for LI_RADS-graded lesions as LR-3 or LR-4; detecting arterial phase hyperenhancement (APHE) when it is absent on CT or MRI, but still suspected; guiding liver biopsies or treatments for difficult to visualize lesions, aiding in choosing the right lesion to be biopsied or reevaluating prior biopsied lesions with inconclusive histopathology; assessing treatment response; making the differential diagnosis between a tumor inside a vein or a simple thrombus [15].

One of the most important indications for CEUS is liver mass characterization and not just detection, with some studies showing an equivalence or even a superiority compared to CT or MRI scans. This ultrasound can also help in differentiating benign from malignant nodules [16].

The most common benign lesions that can be diagnosed using CEUS are hemangiomata, focal nodular hyperplasias (FNH) and hepatic adenomata. Malignant masses which are evaluated by CEUS are hepatocellular carcinomata (HCC) and non-hepatocellular tumors, that include metastases, intrahepatic cholangiocarcinomata (ICC) and lymphomata [16–18].

Liver lesions in CEUS can be described using two features that appear in different phases of the ultrasound: arterial phase hyperenhancement (APHE) and washout [1,16].

If there is no washout present and the enhancement in the arterial phase is sustained, there is a high probability that the mass is benign. In comparison, malignant masses show a decline in the enhancement (washout) in the portal or late phase. Furthermore, the intensity and the timing of the washout can be employed to differentiate between types of liver malignancies.

HCC nodules are most likely to display a late (in over 1 minute) and weak washout, while non-hepatocellular malignancies exhibit early (in less than 1 minute) and intense washout. In order to detect liver metastasis, a sweep of the entire liver in the portal venous phase is essential [1,2,16,17,19]. The benign lesions are usually described by specific patterns of enhancement in the arterial phase. Some examples of these patterns are peripheral discontinuous nodular enhancement (hemangiomata), stellate vessels with centrifugal filling (FNH) and centripetal filling (some adenomata) [16,20].

TECHNICAL EXECUTION

To correctly perform an ultrasound using contrast agents, firstly, it is necessary to have a properly trained examiner who should be able to recognize focal liver lesions and vascular disorders, to assess the effect of a treatment over a lesion and to compare different findings with other imaging methods such as CT, MRI or PET-CT. Secondly, the ultrasound equipment needs to have appropriate hardware, for example, scanners that can cancel soft-tissue enhancement, and software that can display both the standard ultrasound image and the CEUS image simultaneously [15,16]. The patient should be in a supine position with the abduction of the right arm, and before injecting the agent, the examiner should be aware of the medical history of the patient, of the clinical aspects and also of any existing cysts or calcifications that may be wrongly interpreted as malignant [1,12,15,16,21].

For liver imaging, the recommended dose of SonoVue, the most frequently used contrast agent, is 2.4 mL. This value can be decreased by 20-25% if the patient has a low BMI in order to avoid the excessive enhancement of the liver or it can be increased if the lesion is very superficial [15]. The substance is then injected through a large IV line (20-gauge minimum) as a bolus in the span of 2-3 seconds, immediately followed by a saline flush of 5-10 mL [2,7,15].

Interpretation of CEUS is made by evaluating the three vascular phases that follow the injection of the contrast agent. These phases appear as a result of the double vascularization of the liver, namely the hepatic artery and the portal vein [21].

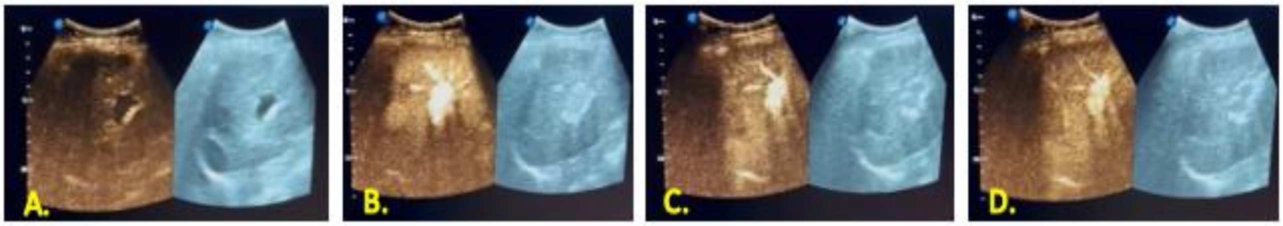
The arterial phase begins at 10 to 20 seconds after injection and ends at 30-45 seconds and appraises the arterial vascular supply of the liver lesion by degree and pattern [1,21]. The portal venous phase begins immediately after the arterial phase at 30-45 seconds and can last up to 120 seconds (2 minutes). This phase marks the entry of the contrast agent in the portal vein and is characterized by diffuse and maximal enhancement of the liver parenchyma [1,21]. The late phase is represented by the amount of time passed from the end of the previous phase until the clearance of the contrast agent from circulation and it can vary from 2 to 8 minutes (120–480 seconds), depending on the type and dose of the agent [1,21]. The post-vascular phase only appears if Sonazoid is injected and it is the result of the contrast loading of the Kupffer or other phagocytic cells. This particular phase usually starts after 8 minutes (480 seconds) following the initial injection and can be seen even after several minutes or hours [1,21] (Table 1).

Table 1: Vascular phases and their duration in contrast-enhanced ultrasound (CEUS)

	START	END
Arterial	10-20 s	30-45 s
Portal venous	30-45 s	120 s
Late	>120 s	Approximately 4-8 min (bubble disappearance)
Post-vascular	>480 s	Approximately 30 min

In the following images, an HCC nodule can be seen during a contrast-enhanced ultrasound. The hyperenhancement in the arterial phase and the late and mild washout in the later phases should be noted (Figure 1).

Figure 1: HCC nodule as seen during CEUS. (a) After 0 seconds (moment of contrast injection), (b) After 30 seconds (arterial phase); (c) After 90 seconds (portal venous phase); (d) After 140 seconds (late phase). Image credits: Teodora Isac.



BENEFITS

The contrast agents used for CEUS have a few major advantages in comparison to those used for CT or MRI. The most important characteristic is the increased safety of administration, with almost no side effects reported in the literature. There is no evidence of either cardiotoxic, nephrotoxic or hepatotoxic events, nor any interference with the thyroid function as they do not contain iodine and no need for any specific laboratory testing or fasting before the procedure [2,15,21]. Therefore, these contrast agents can be harmlessly administered to patients with renal failure and CEUS can be considered the first-line imaging method for these particular cases [2,21]. Some studies show that when adverse reactions do appear, they are: headaches, chest pain or chest discomfort and nausea, all other symptoms being extremely rare [21,23,24].

Compared to CT contrast agents, CEUS agents have a significantly lower incidence of hypersensitivity events and the probability of an anaphylactoid-type reaction is extremely low, with a rate of 0.001% and a rate of 0.0006% of fatalities after SonoVue administration [2,21]. Some studies show that CEUS is also safe for use in pediatric patients or pregnant women [21]. Following these observations in the population, the 30-minute period of monitoring previously recommended after injection of contrast agents was eliminated [15].

CEUS has the advantage of being a real-time investigation with a higher sensitivity for detecting APHE in focal liver lesions than CT or MRI and is one of the most important imaging methods for identifying HCC nodules [6,21]. CEUS can categorize a rapidly enhancing hemangioma as LR-1, often wrongly diagnosed as LR-3 or LR-4 by CT or MRI, and can also differentiate an arterioportal shunt from a true HCC nodule, which can confuse the previously mentioned types of scanning [6].

CEUS was successfully employed for guiding treatment procedures or for evaluating treatment response. When performing a US-guided thermal ablation of a liver nodule, often an HCC one, CEUS showed a rate of 95.2% of patients with complete tumor ablation after a single procedure compared to 32% of patients after using a standard US. The rate of tumor recurrence was reduced to 16% as compared to 48% and the patients that benefited from CEUS guidance showed better progression-free survival rates [16,25,26]. The sensitivity of CEUS for post-treatment assessment is more than 80% and the specificity nears 100%, in some studies exceeding other imaging modalities, and, if used immediately after the ablation, is able to evaluate hemorrhages or hepatic infarctions [26].

Another treatment procedure after which CEUS can be used to determine residual tumor is transarterial chemoembolization (TACE). When employed after 4 weeks, it can successfully differentiate between a real active tumor and post-procedural inflammation. Some studies show that CEUS can visualize residual HCC nodules after only 1 day following the procedure, with higher rates of detection than CE-CT after 1 month [25]. It also has the advantage of detecting smaller areas of viable tumor that cannot be correctly appreciated by CT or MRI [26].

Though limited, there are studies that attest to the use of CEUS for evaluating patients one week after transarterial radioembolization (TARE) based on its ability to detect changes in tumoral perfusion [26].

Some studies evaluate CEUS as a monitoring tool for systemic therapies and their effects on tumor angiogenesis [25].

LIMITS

Even if CEUS is one of the most efficient imaging methods for liver nodules, there are some limits that need to be taken into consideration.

First of all, being a real-time evaluation, it is not possible to examine more than one lesion at the same time or to visualize the entire liver in the arterial phase; for this instance, a second bolus of contrast agents is needed for the same patient [2,15]. For patients with multiple liver nodules, contrast-enhanced CT or MRI is recommended [22].

Secondly, areas that are difficult to examine on a standard ultrasound are most likely the same when using CEUS and it can be troublesome when the lesion is smaller than 10 mm or is located subdiaphragmatic or very deep [15,22]. Small, simple cysts can be misinterpreted as metastatic lesions because both of them appear hypoechoic on CEUS [2].

For nodules that require complete imaging staging or monitoring of changes in size over time, CT or MRI are more likely to be of use, because CEUS alone is either not sufficient or it is very difficult to capture exactly the same image as the first time on serial US exams [6,22,27].

Even though CEUS is better than standard US, it is still examiner-dependent and the quality of the images may differ with movement artifacts or other interferences [2]. Some limits may also appear in the technique itself, for example, artifacts related to the dosing of the contrast agent, destruction of the microbubbles by the US beam, or inadequate tissue suppression as seen in a fatty liver [16].

CEUS LI-RADS and HCC

In order to create standardized reports for liver nodules, mainly HCC, seen on CEUS examinations, a scoring system has been designed called LI-RADS (Liver Reporting and Data System) [1,28,29]. It helps improve communication between different examiners and reduce confusion and diagnostic errors in patients with high risk for HCC [28]. The nodules observed with CEUS are then classified as: LR-1 (definitely benign), LR-2 (probably benign), LR-3 (intermediate malignancy probability), LR-4 (probably HCC) and LR-5 (definitely HCC) [1,28] (Table 2). Because CEUS is also able to evaluate other types of liver masses, additional categories have been added: LR-M (malignant, but not specific for HCC), LR-TIV (tumor present in the vein) and LR-NC (not categorized due to omission or image degradation) [1,15,30,31]. The sensitivity of CEUS for detecting HCC lesions is dependent on the mass size. For nodules of less than 2 cm, the sensitivity can vary in different studies from 53.6% to 83.3% and for nodules bigger than 2 cm, it ranges from 91.3% to 94.5%, with a mean of approximately 78.3% and a specificity of around 93.1% [32].

If a nodule shows rim-like APHE, which means the enhancement is more intense in the periphery, forming a halo around it, the category according to CEUS LI-RADS should be LR-M and they are usually liver metastasis or other malignant lesions, but not HCC. If the nodule has a peripheral discontinuous globular pattern, it should be included in the LR-1 category as a benign hemangioma [1,33].

Table 2: CEUS LI-RADS diagnosis (modified after [6])

APHE (arterial phase hyperenhancement)	**NO**		**YES** (not rim and not peripheral discontinuous globular)	
Rim APHE or early washout (<60 s) or marked washout – LR-M Peripheral discontinuous globular – LR-1 (hemangioma)				
Nodule size	Nodule size	≥20 mm	<10 mm	≥10 mm
No washout	LR-3	LR-3	LR-3	LR-4
Late and mild washout	LR-3	LR-4	LR-4	LR-5

In a study that took place between January 2010 and December 2018, 382 patients (with a total of 464 liver lesions) with chronic liver disease at high-risk for hepatocellular carcinoma were included [28]. The exclusion criteria were: transarterial chemoembolization, radiofrequency ablation, and systemic treatment for HCC [28]. The 464 liver lesions were divided into: 68 non-HCC non-malignant lesions (hemangiomata, simple cysts, fatty infiltration, regenerative nodules), 359 HCCs and 37 non-HCC malignant lesions (liver metastases, other types of malignancies). By using CEUS LI-RADS, all of the 464 nodules were classified and the percentage of HCC was established for each category. From the total number of lesions examined, 22 of them were part of the LR-1 category and the other 8 lesions were classified as LR-2. Among those, the HCC rate was 0%. 26 lesions were included in the LR-3 class, but 11 (42.3%) of them were HCC. From the 106 nodules that were included in the LR-4 category, 85 (80.2%) were also confirmed to be HCC. 264 nodules from the total of 464 were categorized as LR-5 by means of CEUS and the HCC rate in this category was 258 (97.7%). For the remaining lesions, 11 were classified as LR-TIV and all of them (100%) were confirmed as HCC, and 38 were classified as LR-M; only 5 (13.2%) of those actually were HCC [28].

The sensitivity of the LR-5 category for the diagnosis of hepatocellular carcinoma was 71.9%, with a specificity of 94.3%, a positive predictive value of 97.7%, a negative predictive value of 49.5% and an overall diagnostic accuracy of 76.9% [28].

By combining the LR-4 and LR-5 categories, they managed to improve the diagnostic accuracy to 90.7%. In this case, the sensitivity was 95.5%, the specificity 74.3%, the positive predictive value 92.7% and the negative predictive value 82.9% [28].

This study has once more shown that CEUS is comparable to CE-MRI and CE-CT in the diagnosis of hepatocellular carcinoma and can be used as a first step to describe liver lesions in high-risk patients during the HCC surveillance. Moreover, using CEUS instead of CT/MRI limits the use of unnecessary imaging techniques in the case of non-malignant tumors [28].

Differentiating an intrahepatic cholangiocarcinoma from a hepatocellular carcinoma in patients with liver cirrhosis can be difficult. The CEUS pattern of the intrahepatic cholangiocarcinoma in this study was a heterogeneous and rim-like enhancement in the arterial phase and a portal venous and late vascular phase washout. The key feature of the HCC is represented by the arterial hyperenhancement of the nodule, followed by a late (after one minute) or absent washout [28]. CEUS has shown a good performance in the diagnosis of HCC, with good sensitivity and specificity using the LI-RADS algorithm. However, an HCC nodule lower than 2 cm has shown a lower sensitivity (56.3%) as compared to 78.9%, representing the sensitivity of HCC nodules higher than 2 cm.

In spite of all the limitations of CEUS presented in this study, the CEUS LI-RADS algorithm for HCC diagnosis remains a useful non-invasive clinical practice [28].

In conclusion, for a nodule to be diagnosed as HCC, it needs to show an APHE, not rim-like and not peripheral discontinuous globular patterns and late and mild washout, as compared to other malignant lesions of the liver categorized as LR-M, that reveal a rim APHE and early, marked washout [30,31,33].

Specific HCC-related conditions and CEUS contribution

CEUS could help differentiate AFP-negative hepatocellular carcinoma from other liver malignancies. A total of 99 patients with liver disease and AFP-negative primary liver malignant tumors were included in a study that took place between January 2018 and February 2021. While the inclusion criteria were the following: serum AFP negative for all patients, the CEUS LI-RADS criteria applied to all patients and CEUS performed within 2 weeks before the liver surgery or biopsy, the exclusion criteria were the following: tumor lesion below 1 cm, thrombosis of the vein, multiple tumors, other treatment modalities in advance of the CEUS examination [28]. They performed CEUS using Siemens ACUSON Sequoia and Philips IU22/EPIQ7 and SonoVue as the contrast agent [33].

According to the results of the biopsy, the 99 intrahepatic lesions were divided into 38 cases of other malignancies (3 cases of HCC combined with ICC, 31 cases of ICC, 3 cases of lymphoma, 1 case of spindle cell sarcoma and 1 case of angiosarcoma) and 61 cases of HCC [33]. The study showed that there were no patients in the LR-1, LR-2 or LR-3 categories in both the HCC group and the OM group. In the HCC group, there were 13 patients in the LR-4 category, 38 patients in the LR-5 category and 10 cases in the LR-M category, while in the OM group, there were 3 patients in the LR-5 category and 35 cases in the LR-M category [33].

The table below shows the sensitivity, specificity and both positive and negative predictive values for the diagnosis of hepatocellular carcinoma or other liver malignancies using the CEUS features [33] (Table 3).

Table 3: CEUS characteristics and their efficacy in the diagnosis of both HCC and OM
(modified after [33])

HCC characteristics	Sensitivity	Specificity	Positive predictive value	Negative predictive value	Diagnostic compliance rate
APHE (but non-rim)	95.1%	63.2%	80.6%	88.9%	82.8%
Mild washout	88.5%	65.8%	80.6%	78.1%	79.8%
Late washout	75.4%	84.2%	88.5%	68.1%	78.8%
LR-4	21.3%	97.4%	100.0%	44.2%	51.5%
LR-5	62.3%	92.1%	92.7%	60.4%	73.7%

Other primary malignancies (OM)	Sensitivity	Specificity	Positive predictive value	Negative predictive value	Diagnostic compliance rate
Rim APHE	57.9%	96.7%	91.7%	78.7%	81.8%
Marked washout	65.8%	95.1%	89.3%	81.7%	83.8%
Early washout	84.2%	82.0%	74.4%	89.3%	82.8%
LR-M	92.1%	83.6%	77.8%	94.4%	86.9%

Although AFP is a serological marker of great importance in the early screening of HCC, there is a important number of patients who are AFP-negative and present intrahepatic nodules. Therefore, CEUS is a safe, convenient, cost-effective and radiation-free tool that can reveal microvascular vascularization of the tumor. However, it may be difficult to differentiate HCC nodules from ICC nodules in cirrhosis due to the overlap between the enhancement patterns [33].

This study shows that the LR-5 category has a specificity of 92.1% for HCC nodules that are AFP-negative and a specificity of 62.3%. The LR-M category represents an optimal way to differentiate other liver malignant lesions from HCC nodules. The LR-M category in this study revealed a sensitivity of 92.1% and a specificity of 83.6%. [33] Moreover, CEUS LI-RADS has a great application value for the diagnosis of HCC versus OM in patients at risk of HCC. CEUS LI-RADS can be used to determine the presence of focal intrahepatic lesions, even at an early stage when AFP is negative. Nevertheless, CEUS LI-RADS needs continuous improvement in order to diagnose and differentiate other liver malignancies efficiently [33].

Furthermore, CEUS proved to be helpful in the evaluation of the post-treatment response in patients who underwent transarterial chemoembolization (TACE) for HCC nodules. TACE is a therapeutic option widely used for unresectable hepatocellular carcinomas, given the fact that the majority of patients with HCC are usually diagnosed when the disease is at an advanced stage [34]. Patients who underwent TACE as treatment for HCC need to be accurately evaluated to establish the subsequent plan of therapy. CEUS can depict tumor necrosis after TACE, as early as 1-2 months, while the shrinkage of the tumor can take longer to occur [34]. This study wanted to describe the patterns of residual HCC on CEUS and compare the accuracy of CEUS with that of CT in the assessment of HCC response to TACE [34].

This study took place between February 2010 and June 2015 and included patients with HCC who had undergone TACE. They were divided into two groups: those who were assessed for the very first time after the procedure for tumor response and those who were suspected of tumor recurrence due to raised serum AFP.

The inclusion criteria in the study were the following: single mass or multinodular HCC less than 50% of the liver, entire nodule seen on standard US, nodule smaller than 15cm, while the exclusion criteria were represented by the presence of comorbidities (renal and heart failure), severe cirrhosis, HCC involving more than 50% of the liver and breastfeeding women. After applying the exclusion criteria, 50 patients with 70 liver lesions were evaluated by CEUS, but only 57 masses by CEUS, CT and MRI [34].

MRI detected residual disease in 36 masses out of 57; meanwhile, CEUS successfully identified 34 out of 36, resulting in a sensitivity of 94%. The specificity of CEUS compared to MRI was 100% regarding the 21 masses with no recurrent disease. The positive and negative predictive values of CEUS were 100% and 91% [34].

Compared to the multiphase CT, the sensitivity of CEUS was 94% (vs. 50%), while the specificity was 100% for both imaging tools. These results may be explained by the Lipiodol substance used for TACE, which may appear similar to a residual viable tumor. Therefore, the CT scan may be confusing, while CEUS, by not being affected by Lipiodol, can detect even tiny nodules as early as one week after TACE. After 4 weeks post-TACE, CEUS achieved superior sensitivity rates than CT and MRI (100% vs. 50%) [34].

CEUS could be considered an effective alternative technique for identifying early tumor response of HCC after TACE (using Lipiodol substance). However, it is recommended that, in the long term, CEUS be used together with MRI/CT for a better evaluation of the tumor response [34].

CONCLUSION

CEUS is a real-time imaging method used in many areas of interest, including the study of liver masses. It is shown in many studies that the sensitivity and the specificity of CEUS compared to CT/MRI are similar, or even superior, in the diagnosis and surveillance of hepatocellular carcinoma and other malignant liver nodules. The contrast agents used by CEUS are eliminated throughout the lungs, showing no evidence of hepatotoxic, nephrotoxic, or cardiotoxic events. In order to systematize the assessment of the HCC nodules, the CEUS LI-RADS classification was introduced.

Ultimately, although CEUS has its limitations, there are great perspectives in the appraisal of liver nodules using this imaging technique. The accessibility and safety of the procedure and the absence of the use of ionizing radiation reinforce the idea of using CEUS in the near future as a stand-alone technique in the diagnosis and evaluation of the response to TACE for the hepatocellular carcinoma nodules.

Abstract: Combat medics must deploy multiple cognitive, manual, and social skills to perform efficient life-saving interventions and ensure the safe transportation of casualties. In 2021, the Tactical Medical Training Cell of the Belgian Army introduced an immersive and integrative educational program for Advanced Emergency Medicine Technicians (EMTa) certification. This study aims to provide a correlational analysis of performance outcomes during the certification period. While conducting their assessment, candidates were evaluated in three different but complementary roles: Medical Leader (ML), Medical Practitioner (MP), and Tactical Leader (TL). The individual outcomes in theoretical and practical examinations of one hundred thirty-seven candidates were collected during 2021 and 2022. The mean success scores for the theoretical and total practical examinations were 90.6% and 80.1%, respectively. Candidates scored significantly better as TL. Theoretical results were significantly correlated with the ML function, and performances in all three positions were correlated with each other. This study showed that within the combat medic team, individual performances, even if initially well-defined, were associated with the success rates of the other positions. This finding should be considered in the further consolidation of combat medic education.

Keywords: military medicine; education; first aid; combat medic; tactical leader; emergency medicine

INTRODUCTION

In today's operational theaters, combat medics must deploy multiple cognitive, manual, and social skills to perform efficient life-saving interventions, provide basic medical and nursing care, and ensure the safe transportation of casualties off the battlefield. In a contemporary warfare environment, first-line healthcare professionals face disruptive tactical challenges and novel technological threats [1]. Due to these particularly complex working conditions and this broad spectrum of responsibilities, educational and training programs must emphasize a strong knowledge base and intense practice of basic and advanced damage control resuscitation and surgical procedures. Furthermore, when combined, this knowledge and these skills should stimulate agile physiological thinking, appropriate clinical prioritization and time management, and the conservation of material and human resources, while considering cultural differences and ethical issues where necessary [2].

The integration of adult education principles can actively contribute to enhancing these learning performances. Adult education is defined as a teaching model that incorporates strategies of student self-direction toward goals of practical relevance for the learner [3]. According to Illeris, learning has individual cognitive, emotional, and external environmental dimensions [4]. An integrative and cross-fertilization process – the start of any learning process – takes advantage of five types of stimuli: (a) perception of the raw material; (b) transmission by another person (e.g., in lectures and instruction or through questions); (c) experience; (d) imitation; and (e) participation [5]. Consequently, accommodative and transformative learning that enlarges stimulation modes can contrast with restricted cumulative and assimilative learning. More specifically, theories of adult education aim to value the prior learning and experience of adults [6]. In a systematic review of faculty development initiatives designed to improve teaching effectiveness in medical education, the use of experiential learning, feedback, and effective peer relationships was found to be paramount to the success of these programs [7].

However, for a long time, the superiority of adult education principles in the specific domain of healthcare professionals' education was a matter of debate [8-10]. Interactive learning methods can be used in new contexts that do not resemble the original learning situation [8]. Scientific evidence supports the view that multimodal

and interactive learning principles can lead to higher performance during medical education and training [11-13]. Additionally, problem- or case-based learning appears to promote greater critical thinking, better integration of facts, and improved self-evaluation compared to traditional teaching models with teacher-directed learning and non-interactive modes of teaching [14].

Although these principles of adult learning have been well-described for over 50 years, comparatively little is known regarding their integration into combat medic education or training programs.

In 2021, the Belgian Defense, Tactical Medical Training Cell (TacMed) introduced an integrative and immersive model of an educational program in the Advanced Emergency Medicine Technicians (EMT) certification. All Combat Medics candidates for the advanced course are systematically exposed to this learning model. The principles of the course shape theoretical and practical skills as support for individual professional development and, by extension, leadership maturing. The essential components for individual and collective medical training were identified following the NATO SOF doctrine [15]. Different training principles, such as Life Tissue training (LT) and simulation with role players (SIM), are combined. The last serves as a core education pivot because of the abundance of peer-reviewed evidence from military studies that clearly demonstrates that training methods using human patient simulators for teaching trauma care skills were superior and more cost-effective than many other learning techniques [16]. Finally, specific efforts are put into hyperrealistic and immersive simulation training scenarios as stimulators of team performance [17]. Like other authors [18,19], the course organizers conceived team performance as a multilevel process that includes the interrelation between individual-level and team-level taskwork and teamwork processes. The coordinated activities of a team of well-educated and trained individuals were considered the main objective [20,21].

The primary objective of the study was to establish, within an integrative hyperrealistic education model, the associative principles between theoretical and practical domains in order to explore global performance outcomes. As a secondary objective, success rates for specific achievements were inventoried, and a complementary analysis of their association profiles was performed.

MATERIALS AND METHODS

Study design

Advanced Combat Medic candidates presenting at the Medical Component Competence Centre, Belgian Defense, were included in this single-center retrospective cohort study.

Study setting and data collection

This study was carried out from January 2021 to December 2022. Instructors, evaluators, and Exercise Controllers systematically collected and processed all theoretical and practical examination results.

Population

A yearly refresher Tactical Combat Casualty Care (TCCC) educational program must be attended by all Belgian soldiers. The operational units of the Belgian Medical Component and combat units, including Special Operation Forces, detached their Combat Medic candidates. In their respective units, they applied voluntarily for a specific position as first-line responders. All candidates were consecutively included. To exclusively explore the course benefits, only students who failed the entrance examination were excluded from this study.

Intervention

A three-week theoretical module covering TCCC, Pre-Hospital Trauma Life Support (PHTLS), and Advanced Medical Life Support (AMLS) principles is preceded by an initial entrance exam on general anatomy and physiology. At the end of this sequence, and after succeeding in the theoretical exam in these domains, a three-week practical module is launched. This module includes dead tissue training, trauma patient simulation (using role players or manikins), clinical scenarios (individual or team-based), and a broad spectrum of clinical practicals. These are focused on amphibious medical incidents, mass casualty situations, complex casualty extrication, and CASEVAC (Casualty Evacuation). During a 72-hour final synthesizing on-field examination, all candidates were evaluated based on three independent secondary domains: their capability to act as Medical Practitioner, Medical Leader, and Tactical Leader.

Continuous monitoring by experienced healthcare professionals and psychologists during the on-field certification period ensured adherence to ethical guidelines and psychological safeguards.

Outcomes

Two main domains (total theoretical and practical scores at the final examination) and three practical secondary domains were considered as performance outcomes. The three practical secondary domains were designed to cover cognitive, procedural, and environmental dimensions. These three practical domains were linked to the following positions:

a. The Medical Leader (ML) was responsible for overall clinical assessment and management. The ML's responsibilities included: preliminary medical assessment, medical decision-making, guidance of medical activities, securing medical evacuation, and leadership of medical providers. Evaluation methods for this function assessed the quality of the medical approach (both diagnostic and therapeutic), the effectiveness of control over hard skills by team members, the quality of general clinical guidance, adequate and effective communication with the superior clinical echelon, control of safety rules, and final clinical responsibility.

b. The mission of the Medical Practitioner (MP) was to execute technical medical skills under the leadership and supervision of the ML. Particular attention was paid to the quality of material preparation, completeness, and safety in execution. The specific soft skills evaluated were: empathy towards the casualty, reactivity to ML demands, quality of reporting to the ML, and interaction and communication with the ML and other MPs.

c. Finally, the Tactical Leader (TL) was responsible for team security, controlling situational awareness, and coordinating the medical team's tactical actions. This function was evaluated through quality indicators of situational awareness, safety rules, planning of team actions, and consolidation of the medical evacuation plan proposed by the ML.

Evaluation tools and variables

During the theoretical evaluation, the candidates were evaluated on the percentage of correct responses at the end of the theoretical module. At least two independent evaluators from TacMed scored the respective ML, MP, and TL performances during the practical examination. Concerning the scenarios with role players, three main objectives were preliminarily defined and specifically evaluated through a scoring system reportable on a percentage scale. The first evaluation objective was always dealing with the hard skills, the second with the individual soft skills, and the third with the individual contribution to the collective dynamics.

The evaluators had received the same education and training for this purpose. The education of evaluators respects the NATO standards and includes additional skills from the civilian evaluation systems developed for health care. They regularly train for this function and are obliged to participate in all evaluation exercises organized by TacMed. At least one of the observers is educated and certified in an Observer/Trainer function following the NATO standards (International Military Medical Observer Trainer Course (IMMOT) course, NATO MED-MS-36887, NATO Centre of Excellence for Military Medicine). During the preparation of the scenario, the defined objectives and evaluation tools per objectives are revised together within the evaluator's team. All evaluators use the same evaluation scale.

Evaluators are blinded to theoretical scores and scores from the other scenarios run by the candidate.

The evaluation indicators were independently evaluated by each evaluator and compiled into a final score. The final score for each function was obtained by simple cumulation of the individual scores of all of the examinators. Each candidate went through the different positions at least two times.

The final global practical score corresponded to the sum of all scenarios' scores of the candidate.

In support of this scoring system materials, additional videos or pictures were captured.

At the end of each scenario, during the debriefing, individual and collective learning points were pointed out by each candidate as well as by the entire team.

Statistical analysis

An overall description of all populations/outcomes was statistically explored. Categorical variables were summarized using frequencies and percentages. Continuous variables were summarized using medians and standard deviations (SD). After checking for normality using the Kolmogorov-Smirnov test, the data were found to be not normally distributed (statistic = 0.127; df = 107, $p < 0.001$). The Wilcoxon Rank Sum test was used to compare two groups, paired or unpaired. The Mann-Whitney U and Kruskal-Wallis tests were used to compare a continuous variable with a categorical variable with two or more categories, respectively. Correlations between theoretical/practical results and individual results from the secondary domains were calculated using Spearman's rank correlation, two-tailed. The overall practical results (%) were defined as the dependent variable for multivariate linear regression, with multiple independent variables being demographic or individual results. A p-value < 0.05 was considered statistically significant. Biostatistical analyses were supported by IBM SPSS Statistics Version 29.0.1.0 (171) (License Ghent University, Belgium).

RESULTS

One hundred thirty-seven combat medic candidates for EMTa certification were recruited, and their individual scores were collected. Their participation was well-distributed during the two-year study period: from January 2021 to December 2022 (Table 1). With a mean seniority in the army of 8.99 years (SD = 5.13 years, range = 1-22 years), the candidates had a mean age of 30.30 years (SD = 5.89 years, range = 21-49 years). The vast majority of candidates were male (97.8%), with only 2.2% being female. In the total group, 71.5% of candidates succeeded in the final test, and 9.5% failed. Nineteen percent of the total group did not complete the entire course or final certification examination, mainly due to changed work schedules. Although not statistically significant, older candidates were found to be more resilient regarding non-completion of the course.

Theoretical and practical domains

A mean success score of 90.6% (SD = 6.5%) was found for the theoretical examination. On the other hand, the mean of the total practical examinations was 80.1% (SD = 4.8%) at the end of the 72-hour certification field exercise. All age and seniority groups presented this drop between theoretical and practical results, with no significant difference observed between younger and older candidates.

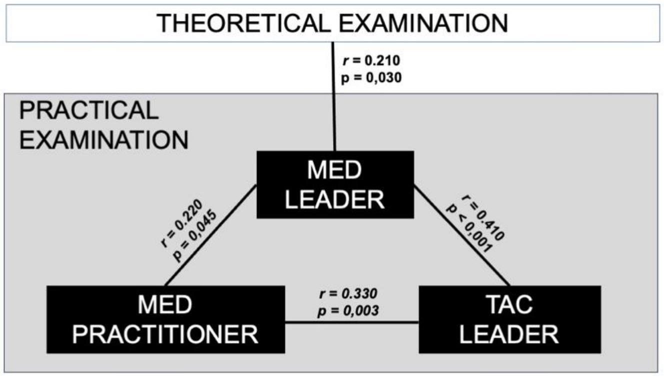
Secondary domains during practicals

The mean results displayed the following respective scores: for the ML function, the success rate was 79.1% (SD = 6.49%); for the MP, 80.8% (SD = 6.28%); and for the TL function, 81.1% (SD = 5.68%). Candidates scored significantly better as TL (p = 0.014) in comparison with their function as ML. When observing the secondary domain success scores, no significant difference was observed between the age or seniority categories.

Table 1: Population characteristics

Characteristic	N	Mean	StdDev	Range
Age (years)	137	30.20	5.89	21-49
Seniority (years)	137	8.99	5.13	1-22
		Count	**Percentage**	
Gender				
Male		134	97.8%	
Female		3	2.2%	
Year of completion				
2021		75	55.5%	
2022		61	44.5%	

Figure 1: Descriptive map of observed associations



Correlations between main and secondary domains

Interestingly, the theoretical results were found to be weakly but significantly correlated not with the total practical score, but only with the ML function (r = 0.210, p = 0.030) (Figure 1). As expected, the total practical scores were significantly correlated with their secondary domains: ML (r = 0.210, p < 0.001), MP (r = 0.565, p < 0.001), and even more strongly with TL (r = 0.793, p < 0.001) functions. Furthermore, the secondary domains were found to be statistically correlated with each other: weakly or fairly but significantly correlated between ML and MP (r = 0.220, p = 0.045), and between MP and TL (r = 0.330, p = 0.003), while the correlation between ML and TL was found to be statistically stronger (r = 0.410, p < 0.001).

Multivariate linear regression

With the total results at the practicals as the dependent variable, the multivariate linear regression identified all practical secondary domains as independent predictors of the total practical results (p < 0.001), with the theoretical results as a weaker but significant independent predictor (p = 0.04) (Table 2). Candidate age and seniority were not found to be predictors of higher performance scores at the final practical examination.

DISCUSSION

In this study, we explored performance scores during military educational and training programs for combat medics. An integrative and immersive combat medic-specific training was proposed in a structured and stratified manner. During the practical examination, three different positions were tested, and this analysis shows how they were associated with each other. During the educational phase of the program, candidates were stimulated in their leadership (medical and tactical) positions through an integrative and cross-fertilization process, taking advantage of five types of stimuli identified by Jensen [5]. On the other hand, the role of the MP was not restricted to the adequate and safe execution of medical hard skills. Although well-structured assessment testing of medical hard skills is beneficial [22], additional soft skills such as communication, reporting, or mutual support were also added to the MP's educational program.

Table 2: Results of regression analyses performed to determine the effect of indicators in predicting performance scores at the practical examination

Objectives of the Course

Our education and training principles were largely inspired by the eight learning fundamentals of Haraldseid-Driftland et al. (2023) – categorizing collaborative, practical, and content elements – to help develop learning principles and tools to translate resilience into healthcare practice [23]. We complemented these with some of the six guiding recommendations of Sousa et al., including simulation, milestones as course learning objectives, and a multi-dimensional, competency-based assessment system [24]. The ultimate goals of this approach were to optimize crew resource management on one hand, and the individual resilience of first-line responders on the other. Especially in healthcare, communication, teamwork, and leadership top the list of nontechnical skills pivotal for clinical success [25,26]. As an illustration, deficiencies in nontechnical skills are among the leading causes of adverse events in the operating room [27,28]. In the early 1990s, Crew Resource Management principles initially developed to reduce pilot errors were applied to the medical field by anesthesia instructors, who developed the concept of Anesthesia Crisis Resource Management [29,30], with later extension to other actors in the operating room [31]. Across levels and contexts, this approach was found to stimulate healthcare professionals to collaborate, adapt to change, maintain processes and functions, and improve quality and safety through interactions such as exchanging information, coordinating, negotiating, aligning needs, and developing buffers [32]. Increased resilience has been shown to positively impact nursing practice by Thomas and Asselin [33]. In this context, resilience appears to be an important asset [34], and resilience-enhancing interventions to prepare healthcare students for their future professional practice were found to be beneficial [35].

Conceiving a Balanced Educational Program

Observing performance results, this study identified statistical associations between different positions within a combat medic team. For instance, in our study, the TL position – even if primarily more oriented towards situational awareness – was associated not only with global performance scores but also with the quality of more specific medical functions. Over the past century, educational psychologists and researchers have posited many theories to explain how individuals acquire, organize, and deploy skills and knowledge [36,37]. The three different processes of learning identified by Illeris – cognitive, emotional, and social – can occur simultaneously, forming a holistic learning process [4]. Additional dimensions of learning, such as physical or spiritual, could probably be added to this scheme.

At a cognitive level, our study has shown that the execution of medical techniques is not simply linked to previous knowledge acquisition. MP performance was correlated with the presence of two leading functions. Based on our methodological limitation of using a retrospective observational protocol, we cannot establish any intrinsic causal strength. Cognitive learning theories support the view that learning is a targeted internal process focusing on thinking, understanding, organizing, and consciousness. Even if successful in many learning aspects, such as information processing, curiosity stimulation, and motivation, they were found not to be strong enough to transfer the required knowledge to all learners. Additionally, they require considerable time and a trained workforce [37]. This evidence justified our choice not to exclusively concentrate on hyperrealism or single structural fidelity. We hypothesized that it may be more productive from an educational standpoint to consider the fidelity of the simulation scenario relative to clinical task demands along with physical resemblance [38-41], referring to evidence from the literature in this field [39-44]. This advantage of using multimodal simulation was supported by recent literature [42,43,45,46].

The emotional dimension of learning was not specifically explored in our study. However, our educational approach took advantage of an additional social dimension by encouraging and persuading previously learned behaviors, drawing the attention of learners, and creating strong responses [39-44]. Thanks to selective attention and memory, humans learn more from their experiences and organize these experiences into internal representations that facilitate future behavior [40-45]. Passive formats, lack of relevance, and disconnection from students' needs are some arguments supporting the apparent lack of efficacy of formal lectures [38, 46]. It appeared that the candidate's age or seniority in the army was not correlated with performance scores. Seniority and its consequent experience in the army, initially considered as a possible confounding factor or indirect advantage in this integrated learning model, cannot exclusively support the entire learning process. This finding stressed that medical and tactical leadership functions within a Combat Medic team must be learned and trained in addition to acquiring the necessary medical hard skills.

Finally, to emphasize the social dimension of this learning process, we chose event-based assessment as an essential method to deal with the complexity of authentic clinical interactions [47]. It potentially overcomes the shortcomings of not being able to observe tacit behaviors and cognitions and allows team members to assess the unobservable elements of teamwork [48,49].

Holistic Approach for the Education of Combat Medics

Our results only describe performance patterns, and our study was not designed to measure inferences within intrinsic cognitive mechanisms. Further analyses should be conducted to describe causality between indicators, identify all influencers, and measure their respective effect sizes on performance. The reported interactions could be considered the basis for a virtuous circle between these three functional abilities: medical guidance, execution, and external situational vigilance.

First, this study confirmed existing scientific evidence stating that a strong integration of various learning methods or tools leads to solid theoretical and practical results, even when considering specific practical tasks.

Secondly, a strict tasking of ML, MP, and TL functions within a combat medic team facilitated the organization and the detection of medical or tactical issues. These multiple but complementary views on the same medical situation positively influenced the final performance of each individual in the group. This task was initially designed to avoid interference and improve the quality of healthcare. All these tasks appear not to act separately but can reinforce each other. However, this approach imposes complementary education and training in soft skills, such as communication and reporting.

Finally, these considerations are not restricted to the specific environment of the Belgian Army. The program developed by TacMed at Belgian Defense was based on existing national or international protocols and studies, whether developed by or for armed forces or not. It took into account the military culture in Belgium and existing programs in other professional communities. The combination of educational tools was tested and adapted within the military, but external civilian experts adjusted program content or assessment methods. For this reason, some of these findings can be generalized beyond the specific Belgian military context.

Limitations

This study has limitations. The education program benefited from knowledge accumulated from the trainers' expertise, general trends in adult education, and guiding principles in EMT practice. Although efforts were made to minimize their effects, bias and unmeasured factors due to this retrospective design are still an issue. Because of their retrospective and observational nature, correlations could not establish causation between parameters. The conclusions of this study are based on the 71.5% of candidates who successfully completed the certification process. This high attrition rate could introduce a bias towards overestimating competency and positive correlations. Furthermore, the study is subject to all the limitations of a monocentric study design. Finally, while this is a preliminary qualitative investigation of integrative practice and leadership views in a military prehospital context, the perspectives represented may not reflect the entire profession, given the small overall sample size. Despite these limitations, these results provide valuable insight into some performance indicators in a complex work environment.

CONCLUSION

Inspired by recent findings in adult education, our integrative and immersive education program for advanced combat medic certification has demonstrated high success rates at both theoretical and practical levels. Furthermore, the performance levels of the different functions within the Combat Medic team, even if initially well-delimited, were found to be correlated with each other. These reported interindividual interactions open new perspectives for the consolidation of learning outcomes.

Abstract: Preventive medicine plays a crucial role in ensuring the efficiency of healthcare systems, and laboratory investigations represent one of its main pillars. However, achieving an optimal balance between the benefits and costs of testing remains a challenge. Caught between public expectations, appropriate test utilization, and the need for adequate physician training in test ordering, enhancing patients' understanding and knowledge becomes essential. To explore this aspect, a general online survey was conducted, completed by 321 respondents. The results show that, while respondents generally followed physicians' recommendations, many also sought laboratory testing on their own initiative. Direct access to laboratory services - facilitated by the widespread availability of private laboratories - has become a common practice. This raises concerns about the potential overuse of laboratory testing and underscores the importance of further investigating the factors driving patient self-empowerment. Enhancing shared decision-making between patients and physicians is essential to optimize the benefits of testing, minimize unnecessary costs, and reducing the risk of health-related anxiety.

Keywords: laboratory investigations; routine testing; public health; medical education; healthcare overuse

INTRODUCTION

Laboratory testing plays a critical role in the diagnosis, monitoring, prognosis, and treatment of diseases. In modern healthcare, best practice emphasizes the principle of shared decision-making. Although this approach is more commonly applied to therapeutic decisions, it is equally relevant to laboratory investigations and diagnostic testing, as highlighted by Watson et al. While patients rarely request blood tests directly, they often perceive laboratory investigations as a meaningful step in the management of their health condition and as an indication that their physician is taking their concerns seriously. For patients, laboratory results are expected to provide clear answers or solutions, whereas physicians typically use them as tools to rule out serious conditions and to guide clinical reasoning. Due to the discrepancy between patients' expectations and the lack of adequate explanations regarding the actual purpose of the investigations, some patients are disappointed when the tests do not provide a clear diagnosis or concrete solutions for their medical condition [1].

In the context of individuals' tendency to absolutize the role of laboratory testing - as either a means of validating their health status or resolving medical issues - direct-to-consumer laboratory testing emerges as a form of self-empowerment. This is a challenge for the safety and efficacy of healthcare because it allows patients to obtain test results without physician referral, clinical interpretation, or a clear understanding of the limitations related to the test's analytical and diagnostic performance or its overall quality [2].

In the context of an increased volume of test requests, there is a potential for negative consequences. When performed by physicians, ordering unnecessary tests may lead to overdiagnosis, which can result in unwarranted treatments, potential adverse effects, and increased costs for the healthcare system. Contributing factors

include patient expectations and pressure, as well as physicians' fear of legal liability, all of which may influence the decision to order tests that are not clinically justified [3].

Furthermore, the education and training of physicians in ordering adequate laboratory investigations might be a challenge. According to a study conducted by Fung et al., the majority of residents in family medicine ordered appropriate tests from a list of 38 laboratory investigations for prevention and screening purposes; however, the majority of the participants ordered at least one inappropriate test per patient (average from 3.3 to 5.7 per patient), leading to excessive costs. Several factors have contributed to the tendency to order unnecessary laboratory tests, including patient requests, fear of overlooking important clinical details, working in solo practice, and concerns about potential litigation [4].

While the main reason why healthy individuals visit the primary care facilities is preventive check-ups, and in this context, the family physicians order a high number of screening tests, the overuse of laboratory investigations has decreased from 1978 [5].

Considering the major influence in balancing overuse and effective screening of individual perceptions, understanding, and emotional responses regarding the role of laboratory testing, this study aims to provide general insights from individuals living in Romania. It explores their opinions, habits, behaviors, and knowledge related to laboratory testing, intending to inform the design of future representative studies.

MATERIALS AND METHODS

A survey was conducted using an online data collection tool (Google Forms), which included questions with predefined answers. Respondents selected the answers they deemed most appropriate. The questions addressed various topics related to medical laboratory investigations, including knowledge, opinions, habits, and behaviors. Participation in the survey was voluntary; the link to the form was accessible to anyone, and respondents' completion of the survey was automatically considered as consent to participate in the study. An introductory section provided information about the study's purpose.

Data were collected using a general data collection instrument rather than a validated questionnaire, aiming to capture a broad perspective and highlight insights and new areas for research, rather than yielding quantitative and generalizable results.

The data were centralized and analyzed using Microsoft Excel and Google Sheets. Relative frequencies were calculated and presented in tables and charts. This study employed descriptive statistics only, reflecting its exploratory nature and the self-selected sample. Therefore, no inferential analyses were performed, and causal or generalizable conclusions cannot be drawn. Further research with representative samples and appropriate analytical methods is needed to investigate potential associations.

RESULTS

1. Characteristics of the study respondents and health status

A total of 321 respondents participated in the survey, with an average age of 29 years (ranging from a minimum of 18 to a maximum of 81 years). Among the participants, 85% identified as female and 15% as male. Geographically, 22% of respondents resided in rural areas, and 78% in urban settings. The educational and professional backgrounds of the respondents are detailed in Table 1. Notably, 27% reported having no relatives or close friends working in the healthcare field. Regarding self-reported health status, 77% of respondents considered themselves healthy, while 23% indicated they suffered from chronic conditions, as illustrated in Figure 1.

Table 1: Educational and professional profile of the respondents

Level of studies	Middle school	High school	Higher education
	1.5 %	27%	72%
Occupation	Student	Employee	Other
	45%	50%	5%
Study or work in one of the following fields: health, medicine, veterinary medicine, dentistry, pharmacy, biology		No	Yes
		55%	45%

The majority of respondents rated their overall health status as good or very good; however, most also reported being concerned or very concerned about their health, as shown in Figure 2.

Several behaviors were reported by respondents as being associated with their health-related concerns, as presented in Table 2.

Figure 1: The relative frequency of chronic diseases among respondents who reported having illnesses

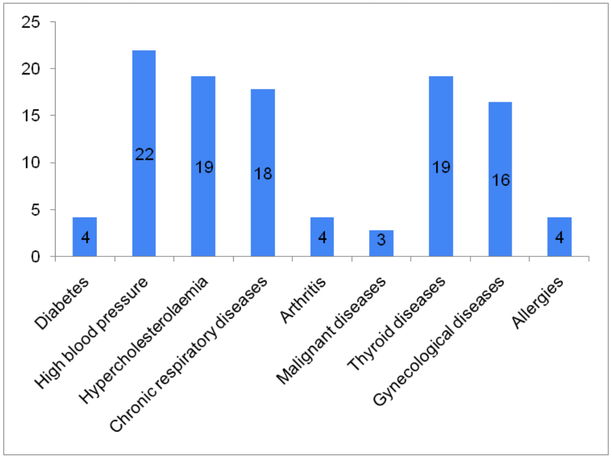

Figure 2. Self-perception of the overall health status (a) and level of concern related to the health status (b)

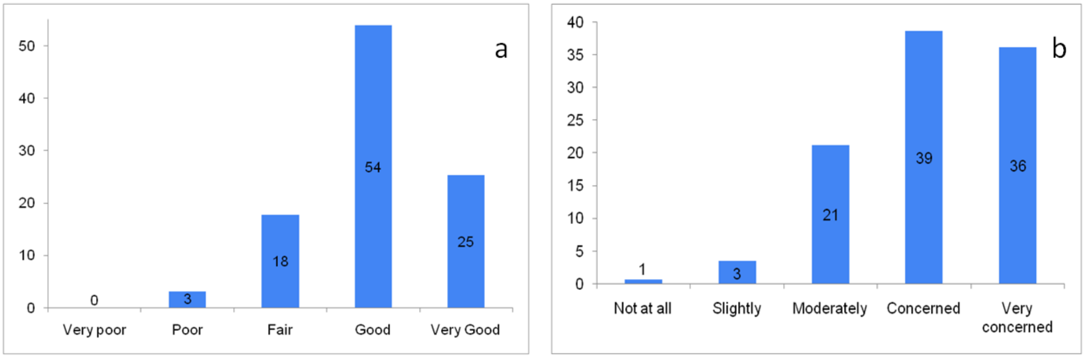

Table 2. Self-reported behaviors associated with health concerns – statements and percentages of respondents in agreement

Behavior linked to health concerns	Relative frequency
I don't consider myself concerned about my health.	4%
I frequently see a doctor for preventive purposes.	28%
I visit the doctor immediately when symptoms appear.	47%
I get medical tests done frequently.	50%
I get laboratory tests done as soon as I notice symptoms.	25%
I go directly to the pharmacy to request treatment if I notice something is wrong.	21%
Concern about my health makes me think about it all the time or frequently.	15%
Concern about my health makes me anxious.	20%
I adopt a healthy lifestyle to be in the best possible health.	36%
I'm afraid of catching infectious diseases in various everyday situations.	26%
I generally postpone going to the doctor for as long as possible.	11%
When I should go to the doctor, I prioritize it over other professional or personal matters.	38%
When I should go to the doctor, I first deal with other professional and personal matters and only then make an appointment.	13%

Opinions about laboratory investigations

Table 3 summarizes respondents' views and knowledge about medical laboratory investigations, their importance, and the recommendations they reported being familiar with regarding laboratory testing.

Table 3: Opinions about laboratory investigations – statements and percentages of respondents in agreement

How important do you consider routine laboratory tests to maintaining health?	
Very important, laboratory tests are essential for detecting and monitoring health problems.	87%
Moderately important, laboratory tests may be useful in certain situations, but are not always necessary.	12%
I do not consider laboratory tests essential for maintaining health.	1%
Do you think it is important to have regular laboratory tests, even if you are healthy?	
Yes, to detect potential health problems in their early stages.	90%
No, if I don't have symptoms, I don't need tests.	2%
It depends on each person's age and lifestyle.	7%
I am not sure.	1%
How well do you think laboratory test results indicate health status?	
The tests show exactly what health problems I have.	25%
Most of the time, the analyses are indicative.	41%
The tests cannot accurately indicate what health problems I have, regardless of their nature.	4%
Certain tests can indicate the exact disease, while others assess the general state of health.	29%
What do you consider to be the ideal approach?	
We should have all kinds of tests done frequently to make sure we are healthy.	51%
We should perform several more important types of tests frequently to ensure we are healthy.	48%
I do not believe that it is necessary to perform routine tests frequently to detect possible health problems.	1%
Do you think that your doctor recommends enough tests for you?	
I didn't need to see my family doctor/specialist.	8%
Yes, I believe I am receiving the necessary recommendations for my health.	63%
I am not sure.	8%
No, I think I am being recommended too many tests.	2%
No, I think that too few tests are recommended for me.	16%
I don't do laboratory tests.	2%
How frequently do you think laboratory tests are recommended for someone your age?	
3-4 times a year	6%
1-2 times a year	83%
Once every 2-3 years	2%
Less often	1%
No specific time frame is recommended	3%
What is your level of confidence in the results of laboratory tests?	
Very high	28%
High	61%
Moderate	11%
Low	0%
Absent	0%
How do you see the doctor's role in interpreting laboratory test results?	
As an essential guide in understanding the results.	90%
Like someone who should only be consulted in case of problems.	6%
I do not consider it necessary to have a doctor interpret it, as there is enough information available on the internet.	1%
No opinion.	2%

Do you think laboratory tests should be used more in prevention?	
Yes, it could help prevent some conditions.	62%
Yes, it could help detect diseases in their early stages.	31%
No, it could cause unnecessary worries.	1%
It depends on each individual case.	5%
How do you evaluate the experience during sample collection for laboratory analysis?	
Comfortable and without problems.	55%
Acceptable, there is potential for improvement.	40%
Uncomfortable and unpleasant.	4%
I have no personal experience in this regard.	1%
Which of the following aspects do you think could improve your experience while performing laboratory tests?	
Reducing waiting time for results.	12%
Lower costs or covered by health insurance.	60%
Better communication and explanation of results.	13%
Reducing waiting time for sample collection.	2%
Do you consider that laboratory results are managed with confidentiality in mind?	
Yes, I trust that they are treated confidentially	77%
I am not sure	15%
No, I have doubts about their confidentiality	2%
I have no personal experience with this	3%
No opinion	2%
Do you think there is enough public education about the importance and usefulness of laboratory tests?	
Yes, there is enough public education.	7%
No, more education would be beneficial.	87%
Not sure.	4%
I don't think public education would make a difference.	2%
No opinion.	1%
When you receive the results of laboratory tests, do you consider it useful to automatically receive explanations of the results in a formal setting?	
No, because I understand all the content and I don't need any other information.	7%
No, because I can find the necessary information by asking people I know or searching the internet.	1%
I do not know.	1%
Yes, I think it would be useful to receive explanations of the results every time I have my lab tests.	88%

Behavior of respondents

Regarding how the respondents deal with the results of medical laboratory investigations, most respondents reported either seeking medical advice or requesting feedback about their health, as shown in Figure 3.

Table 4 presents self-reported adherence to physicians' recommendations regarding laboratory tests, as well as respondents' motivation, testing frequency, and behaviors related to receiving laboratory results.

The majority of the responders reported that the fear of blood or the fear of blood collection does not prevent them from having their laboratory tests done, as presented in Figure 4.

With regard to the entity involved in laboratory investigations, the majority of the responders preferred private laboratories to have their tests done, as shown in Figure 5.

Access, availability, barriers and knowledge related to laboratory testing

In the group of responders who were employed, 48% mentioned that their employer does not provide access to routine laboratory testing, 47% that they have access to routine laboratory testing once a year or more often, and 4% that they have access to routine laboratory testing from their employer every few years.

The responders considered costs and lack of time as the main factors that prevent them from having their routine laboratory testing done, as presented in Figure 6.

Figure 3: Respondents' attitudes toward normal (a) and abnormal (b) laboratory results

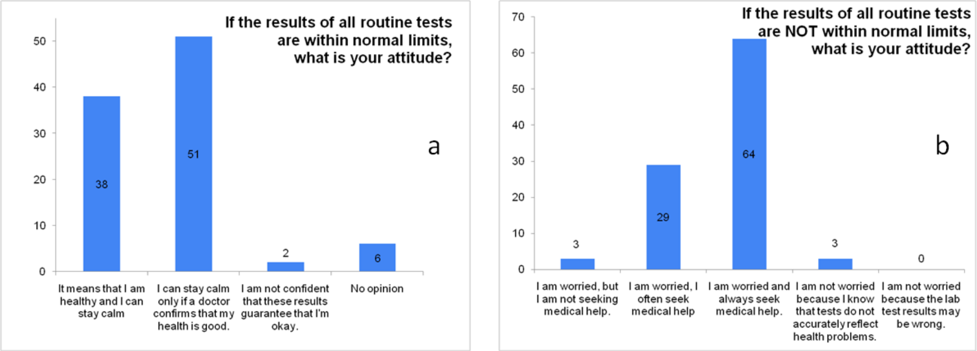

Table 4: Behaviors related to undergoing laboratory investigations, compliance with physicians` indications and dealing with lab test results – statements and percentages of respondents in agreement

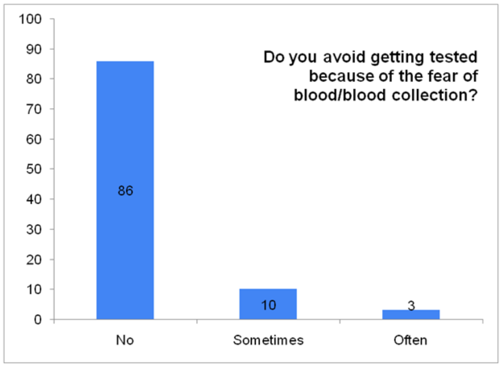
Do you do laboratory tests on your own initiative or on the recommendation of a doctor?	
On the recommendation of a family doctor/specialist.	23%
On my own initiative.	24%
Both on the recommendation of a doctor and on my own initiative.	51%
I don't do laboratory tests.	2%
How often do you do your routine lab tests?	
Twice a year or more often	23%
Once a year	61%
Once every few years	6%
Only when I have a health problem	8%
Never	2%
When you do laboratory tests on your own initiative, what is the motivation? (multiple choice)	
I do not do my laboratory analyses on my own initiative.	14%
I want to make sure that my health remains good.	63%
I want to know if I have a health problem, even if I don't have symptoms.	52%
I have chronic illnesses or other conditions and for this reason, I want to have tests done.	13%
When you performed laboratory tests on the doctor's recommendation, for what purpose were you guided in this direction? (multiple choice)	
To establish a diagnosis.	46%
To follow up a disease.	24%
To perform routine tests without having a health problem.	69%
I did not do any tests recommended by a doctor.	6%
Do you always do your lab tests when your doctor recommends them?	
Always	74%
Often	21%

Rarely	3%
Never	2%
When you don't do lab tests following your doctor's recommendation, what is the motivation? (multiple choice)	
No medical tests were recommended to me.	26%
I was healthy and it was just routine tests.	30%
I did not have enough time.	19%
I did not have access to a collection point/medical analysis laboratory.	7%
I didn't see the usefulness of the analyses in that context.	6%
The costs were too high.	17%
What would you do if your tests are outside normal limits, and the doctor tells you that everything is fine with your health status?	
I turn to another doctor.	35%
I inquire into other sources and make my own decisions for diagnosis and treatment.	7%
I continue the investigations and repeat the tests.	40%
I trust the doctor and do nothing extra.	17%
What is your main source of information regarding laboratory tests? (multiple choice)	
My physician	89%
Acquaintances who work in the medical field	33%
Healthcare related websites	13%
Family, friends and acquaintances who do not work in the medical field	11%
I did not request/seek information about the analyses	3%
Books, magazines and specialized articles	17%
Websites of laboratories and clinics	28%
Social media groups	1%

Figure 4: The impact of the fear of blood or blood collection on having laboratory testing done



The knowledge and opinions about the laboratory investigations reimbursed by the public healthcare insurance system are presented in Table 5.

The majority of the responders have a sample collection facility or a medical laboratory within a reasonable walking distance from their home and reported that the distance from it does not influence their decision to have their routine tests done (Figure 7).

DISCUSSION

Overall, respondents were optimistic about their health status, with most rating it as good or very good. Nevertheless, the majority also reported being concerned or very concerned about their health. This particular perception may influence their attitudes and behaviors related to laboratory investigations. For example, health anxiety has a major impact on healthcare use [6].

Despite expressing concern about their health, fewer than one-third of respondents reported seeking preventive medical care. Approximately 40% reported adopting a healthy lifestyle, and less than half indicated that they consult a physician promptly upon noticing symptoms. More than 60% agreed that laboratory testing could be used more extensively for prevention, and over 30% believed that laboratory tests could be better utilized for early disease detection. However, half of the respondents considered that they already undergo laboratory tests frequently, while only a quarter reported getting tested when symptoms occur.

In general, respondents demonstrated awareness of the importance of laboratory testing for disease diagnosis (including early detection) and monitoring. They also acknowledged that the variety of available laboratory tests serves different purposes in healthcare. While less than one-third expressed very high confidence in laboratory test results, more than 60% reported having confidence in them overall. Additionally, nearly 80% of respondents stated that they trust laboratory investigations are handled confidentially.

Figure 5: Preferences for public and private laboratories

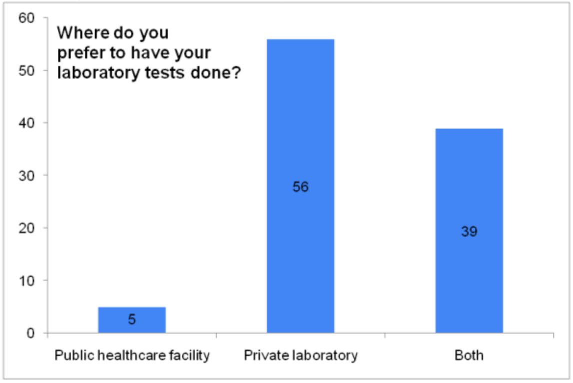


Figure 6. Main barriers to routine laboratory testing

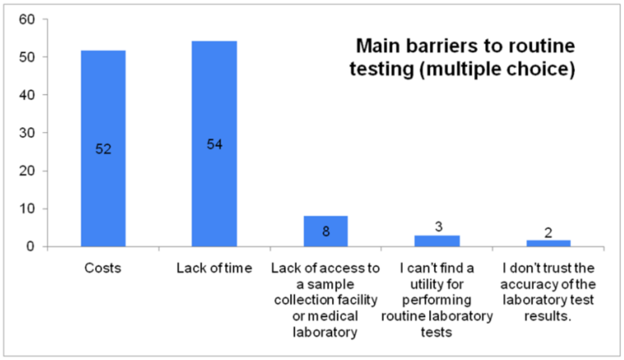

Table 5: Opinions and knowledge of the responders about the reimbursement of the costs for laboratory investigations – statements and percentages of respondents in agreement

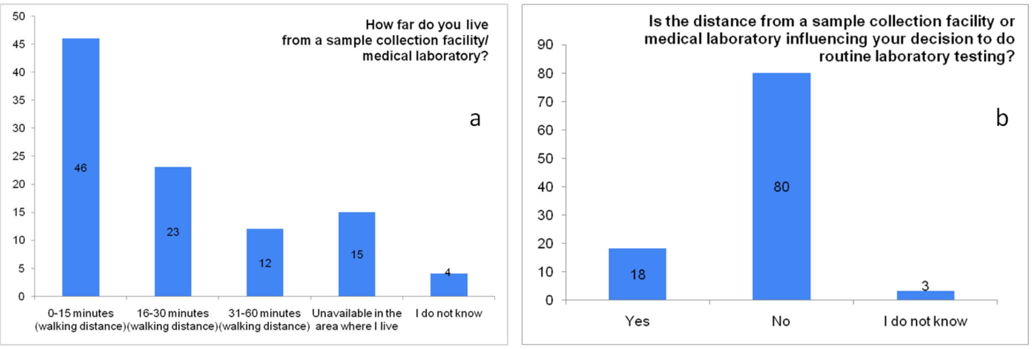
Are laboratory tests reimbursed by the public healthcare insurance system?	
I don't know this information.	30%
Routine tests are reimbursed once a year.	26%
Laboratory tests are reimbursed, regardless of whether they are routine or not, once a year.	4%
Routine tests are reimbursed whenever a referral from the family doctor is used.	33%
Lab tests are reimbursed, regardless of whether they are routine or not, whenever needed.	3%
Lab tests are reimbursed only for those with an established diagnosis.	2%
Lab tests are reimbursed only for hospitalized persons.	1%
Have you ever benefited from laboratory tests reimbursed by the public healthcare insurance system?	
Rarely	15%
Every time/almost every time	21%
Often	36%
I do not know	10%
No	17%

Patients often perceive laboratory tests as inherently accurate and confidential, yet studies suggest gaps in their understanding of these concepts. Sankar et al. highlighted that misconceptions about confidentiality can undermine trust, with some patients overestimating privacy safeguards [7]. Educating patients about the accuracy limits of tests and existing privacy protections may strengthen their engagement and promote informed participation in healthcare decisions [8].

With regard to healthcare received from physicians and the medical system, most respondents considered that, in general, they are adequately recommended for laboratory testing. Overall, routine laboratory testing appears to be driven equally by the respondents' own initiative and by physicians' recommendations. Patients who undergo laboratory testing on their own initiative are motivated by various factors, including the desire to confirm their perceived good health status or personal experiences—such as witnessing family members or acquaintances being diagnosed or saved through timely laboratory testing [3]. The growing availability of direct-to-consumer testing has enabled patients to access laboratory analysis without a physician's mediation, but some studies highlight potential risks, including misinterpretation of results and unnecessary anxiety [9]. According to the results of Shaked et. al, in the case of patient-requested laboratory investigation, even after the doctor explained why the tests were unnecessary, the majority of patients expected to receive a referral for laboratory testing, likely due to the perception that blood tests are objective and reliable tools for validating one's health status [3].

Figure 7: The availability of sample collection facilities or medical laboratory close to the residence of respondents (a) and its impact on decisions regarding laboratory testing (b)



The main reasons for undergoing laboratory tests without a medical recommendation are to ensure good health and to detect early or subclinical diseases. Balancing preventive strategies with patient education about the limitations and risks of indiscriminate testing is essential to avoid fostering a culture of overmedicalization [10]. Approximately 90% of the respondents of this study acknowledged the importance of physicians in explaining laboratory test results. Similarly, nearly 90% believed it would be beneficial to receive explanations of their results in a formal setting each time they undergo laboratory investigations.

Around half of the participants reported that, when laboratory results fall within the biological reference interval, they feel reassured only after receiving confirmation from a physician that their health status is adequate. When routine test results fall outside the reference interval, more than 60% of respondents stated that they always seek medical help, while nearly 30% reported doing so often. According to a study performed by Marloes et al., patients overestimate the performance of blood testing, and results within normal limits were automatically seen as proof of an optimal health status. However, this study included only patients who voluntarily presented to the general practitioner for blood tests [11].

Furthermore, the vast majority of respondents (approximately 90%) identified physicians as their primary source of information regarding laboratory tests. Random online, non-professional sources were not commonly used. Instead, acquaintances working in healthcare and official websites of medical institutions were reported as the second and third most frequently cited sources of information, respectively. On the other hand, a survey by Cocco et al. revealed that an important part of respondents searched for explanations of lab results online before consulting a clinician, sometimes resulting in inappropriate self-diagnosis [12]. McMullan et al. found that patients using online resources for interpreting laboratory results often encounter conflicting or inaccurate information, leading to confusion and heightened anxiety [13].

When routine testing is recommended by a physician, the majority of respondents comply with the recommendation and undergo testing. Among those who do not comply, the main reasons reported are the perception of being in good health due to the routine nature of the check-up, lack of time, and associated costs. Adherence to recommended laboratory testing is essential for effective clinical management, but can be suboptimal. In patients with diabetes, a large registry study found that approximately 1 in 7 did not complete essential lab tests (such as HbA_1c or creatinine) within six months of ordering. Key predictors of better adherence included older age, female sex, and orders placed during face-to-face visits [14].

The majority of respondents considered that routine laboratory testing should be performed once or twice per year. Over 60% reported undergoing routine testing once annually, while more than 20% reported doing so twice a year or more frequently. The optimal frequency for routine blood testing depends on individual health status and clinical context. For healthy adults, many guidelines recommend annual basic panels during preventive visits, but more frequent testing is justified in chronic conditions or medication monitoring [15].

Although fear of blood or blood withdrawal is generally common [16], only 4% of respondents in this study described the sample collection procedure as uncomfortable or unpleasant. Additionally, nearly 90% reported that such fears do not influence their decision to undergo laboratory testing.

From the respondents' perspective, reducing waiting times for sample collection or results, as well as receiving more information and explanations about laboratory investigations and their outcomes, were not considered priorities for improvement. The primary issue identified was the cost of laboratory investigations and their coverage by health insurance.

Cost represents a significant concern, especially given that the majority of respondents reported preferring to have their laboratory tests performed in private laboratories rather than in public healthcare facilities. Additionally, lack of time and financial constraints were reported as the main barriers to undergoing laboratory testing.

Due to the widespread availability of private laboratories in Romania and access to their services without the need for a physician's referral, two specific aspects emerge: firstly, the healthcare system lacks control over potential overuse of testing, and secondly, the costs are often entirely supported by the patient. This situation may differ in other countries, where the overuse of laboratory investigations is potentially driven by the extensive coverage provided by public or private health insurance. When testing is widely accessible and patients and the healthcare provider are not directly burdened by the costs, the likelihood of overuse may increase [17].

Respondents appeared to have limited knowledge regarding the coverage and conditions for laboratory investigations under the public health insurance system, and few reported utilizing reimbursed laboratory tests.

Overall, respondents expressed the view that there should be increased public education regarding the importance and benefits of laboratory testing. Patients often struggle to understand the need for certain laboratory tests and their results, highlighting the importance of public education in laboratory medicine [18].

Overall, the responses to questions regarding laboratory medicine suggest that the general public in Romania may have high expectations for routine testing. Currently, there are no regulations in Romania that restrict access to direct-to-consumer testing. While direct-to-consumer access to routine laboratory investigations is generally permitted across countries, some nations have imposed restrictions on direct access to genetic testing [19]. Although most genetic conditions are rare, for example, familial hypercholesterolemia is a relatively common genetic disorder [20]. In the absence of regulatory limitations, such conditions may be perceived by the general public as suitable for direct-to-consumer testing - particularly given the high prevalence and awareness of hypercholesterolemia. However, this raises the risk of misinterpretation, since direct-to-consumer tests for this condition often lack optimal performance for accurate detection [21].

The current study has several limitations. First, the data collection instrument was not a validated questionnaire, which limits the generalizability of the findings. Additionally, respondents were self-selected, resulting in a sample that is not representative of the general population. Moreover, the sample did not uniformly or comprehensively cover all demographic backgrounds of Romanian citizens, with most respondents holding higher education degrees and residing in urban areas. Finally, all data were self-reported, relying on respondents' subjective perceptions and, in some cases, their memory and ability to estimate the frequency of events (e.g., how often they underwent routine laboratory testing).

However, it is essential to conduct this type of exploratory research, which is less quantitative in nature, to identify key areas for further investigation. This study provided a rapid assessment of various aspects related to patients and laboratory testing, offering a foundation for more detailed future research.

Future studies should build on the exploratory findings of this research by employing validated questionnaires and representative samples to enhance the generalizability of results. Further investigation is needed to understand the multifaceted factors influencing patients' adherence to physician recommendations for laboratory testing, including psychosocial, economic, and cultural determinants. Additionally, evaluating the impact of public education campaigns on patients' knowledge, trust, and behavior regarding laboratory investigations could provide valuable insights. Qualitative research methods, such as in-depth interviews and focus groups with both patients and healthcare providers, would offer a deeper understanding of the perceptions, fears, and informational needs surrounding laboratory testing. It is also important to explore disparities in access to laboratory services across urban and rural settings and among different socio-economic groups. Finally, examining the role of cost and health insurance coverage in shaping patients' decisions to undergo laboratory testing would contribute to the development of targeted interventions to reduce barriers and improve utilization.

Conflicts of interest and sources of funding

The authors declare no conflict of interest. No artificial intelligence automatically generated text was inserted in this manuscript, and no image was previously published in another journal or is under consideration for publication elsewhere. This research received no external funding.

Acknowledgments

The research group was formed with the support of the Medical Research Education Project (https://ssmb.ro/departamente/#scome) of the Medical Students' Society of Bucharest (SSMB).

Ethics approval and consent to participate

This study was conducted using an online questionnaire that was publicly available and open to the general population. Participation was voluntary, self-selected, and anonymous. No personal or identifiable data were collected, and no recruitment of patients was involved. Information about the purpose and nature of the study was provided at the beginning of the form. Completion and submission of the form were considered as an indication of informed consent to participate in the study. Considering all these aspects, the study was conducted in compliance with ethical guidelines.

Abstract: A significant number of neurological diseases are pathogenetically related to oxidative stress, including but not limited to cerebrovascular afflictions such as ischemic and hemorrhagic stroke, Parkinson's disease, Alzheimer's disease, multiple sclerosis, amyotrophic lateral sclerosis, and so on. Natural nutrients may help limit the impact of oxidative stress and, therefore, delay or prevent the impairment of these diseases. Although these natural components have not entered routine use, many have been studied in preclinical or even clinical settings with promising results. Therefore, the need to find the stage of the research in the field of validating the properties and clinical usefulness of such nutrients represents the main reason this narrative review was conducted. This analysis explored the PubMed database for papers related to the influence of natural nutrients on the onset and evolution of some of the most severe neurological disorders. The results of the review provide an overview of the pathways oxidative stress may undertake and how the use of nutrients may counteract these pathways. In conclusion, natural nutrients may have beneficial effects that can be impactful on clinical outcomes, but more good quality research in this field is needed before formulating any clear recommendation.

Keywords: oxidative stress, neurodegeneration, antioxidants, nutrients

INTRODUCTION

This narrative review aims to provide readers with a brief, yet pinpointed overview as to the therapeutic potential of nutritional antioxidants. Given that oxidative stress has a key involvement in the pathogenesis of many neurological diseases (neurodegenerative, cerebrovascular, or inflammatory), targeting oxidative stress through such components (known to medicine for hundreds, if not thousands of years) may prove efficient. Moreover, this paper should be viewed as an incentive to inspire future research, preclinical and particularly clinical, in this field, so that the usage of such components may one day become a validated treatment with a probable wide spectrum. A step-by-step approach to nutrient intervention in neurological diseases is provided in Figure 1.

MATERIALS AND METHODS

Comprehensive research has been conducted by consulting the PubMed database for relevant reports published between the inception of the archive and January 2025.

The following keywords have been used by themselves or in various combinations to achieve optimal results: "Parkinson's disease", "amyotrophic lateral sclerosis", "Alzheimer's disease", "multiple sclerosis", "small vessel disease", "ischemic stroke", "hemorrhagic stroke", "inflammation", "oxidative stress", "reactive oxygen species", "mitochondrial dysfunction", "apoptosis", "necrosis", "excitotoxicity", "lipid peroxidation", "vitamin C", "vitamin E", "coenzyme Q10", "black tea", "green tea", "taurodeoxycholic acid", "flavonoids", "curcumin", "polyphenol", "antioxidant", "Ginkgo biloba", "mecasin", "citicoline", "Artemisia", "Silybum", "curcumin", "melatonin", "saffron", "vitamin D3", "Gastrodia elata", "lavender oil".

Case reports, preprints, and standalone abstracts have been excluded. Only papers published in English were included in the selection.

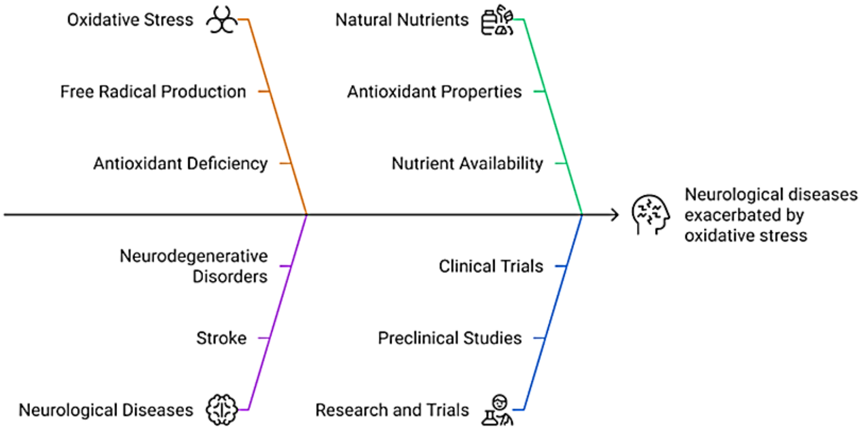
Figure 1: Addressing neurological diseases through nutrient intervention



Oxidative stress is a central component in the pathophysiology of a plethora of neurological diseases. Nutrients may be an appealing method to target oxidative stress and, therefore, mitigate or perhaps even prevent these afflictions. However, the impact of nutrients has to be appropriately measured through validated, reproducible clinical trials before they can broadly enter therapeutic practice.
This figure has been generated using Napkin AI.

RESULTS AND DISCUSSIONS

Parkinson's Disease

Parkinson's disease (PD) is a chronic neurodegenerative disease with a characteristic loss of the dopaminergic neurons in the pars compacta of the substantia nigra [1]. Literature has shown that environmental factors (herbicides, pesticides (such as paraquat), industrial pollutants, neurotoxins (1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine or MPTP) and its metabolite (1-methyl-4-phenylpyridinium), as well as genetic factors (mutations of DJ-1, Parkin, PINK1) [2] involved in PD pathogenesis induce oxidative stress (OxSt) in the mitochondria [3], reduce the production of adenosine triphosphate (ATP), facilitate the generation of reactive oxygen species (ROS), and finally lead to the apoptosis of dopaminergic cells [2].

Pathogenesis

1 Oxidative stress and mitochondrial dysfunction

OxSt contributes to the degeneration of dopaminergic cells in PD [4]. Also, OxSt is tightly linked to other pathogenic mechanisms involved in PD (mitochondrial dysfunction, excitotoxicity, and inflammation); therefore, it is difficult to ascertain whether it is a primary factor in PD or a consequence of the aforementioned mechanisms [3].

In PD, lipid peroxidation is upregulated, and antioxidant pathways (superoxide dismutase – SOD, catalase, glutathione peroxidase – GPx, ceruloplasmin, vitamin E, vitamin C, copper, zinc, selenium) may be insufficient to protect the cells from pathological oxidation [4]. Increased OxSt in association with diminished antioxidant protectors leads to the loss of neurons in the pars compacta, hence the development of PD [4]. Studies have proven lower levels of vitamin C and E in PD patients versus control groups, launching the hypothesis of increased consumption of these vitamins in PD due to OxSt [4].

Excessive ROS production, mitochondrial transport changes, and increased iron deposition in the pars compacta of the substantia nigra are key pathways in PD pathogenesis [1]. There is a close link between ROS formation and mitochondrial dysfunction [1]. Cellular death in PD is thought to be connected to excessive lipid peroxidation, occurring as a consequence of increased oxidation and expenditure of compensatory mechanisms [1]. ROS have a direct cytotoxic impact, as well as an indirect one by impacting mitochondrial complex I, with higher lipid peroxidation [1]. The reduction of this complex leads to the production of more ROS [1].

2 Neuroinflammation

In PD, α-synuclein deposition induces an activation of the microglia in the pars compacta, thus activating nicotinamide adenine dinucleotide phosphate oxidase (NADPH-oxidase) [1]. The latter's consequences are, on the one hand, ROS production in the extracellular compartment afflicting nearby neurons, and on the other hand, redox signaling in the microglia, amplifying the pro-inflammatory response with the induction of chronic inflammation [6].

The presence of excessive OxSt in PD is supported by studies that have proven an increase in carbonyl derivatives [7], in indicators of lipid peroxidation [8], and 8-hydroxy-2'-deoxyguanosine (a marker of nucleic acid damage) [9].

Nutrients

Given the involvement of OxSt in the occurrence of PD and the fact that PD treatment (especially L-dopa) may determine, after a long period of usage, the appearance of free radicals, the administration of multiple antioxidant agents in high dosage along with L-dopa may increase the latter's efficiency [10,11].

In experimental studies, vitamin E was proven to protect cells from OxSt-related damage in PD and the chronic administration of high doses of vitamin E may be a therapeutic strategy in PD treatment or prevention [3,12]. In other experimental studies, vitamin E diminished the OxSt induced by midbrain iron deposits in PD patients, suggesting it may have neuroprotective effects in these patients [13].

Other observational studies on human subjects suggested that a combined administration of high doses of vitamins E and C may determine a slowed PD progression through their antioxidant effect (14), although their efficacy was not proven in double-blind randomized clinical trials (RCTs) [15].

Taurodeoxycholic acid is an antioxidant agent, decreasing ROS reduction, an effect that has been proven when in vivo PD lab models were used [16].

Coenzyme Q10 has an important antioxidant role in the mitochondria and the lipid membrane, some of its antioxidant effects being mediated by its interaction with α-tocopherol. A phase 2 clinical trial on the efficiency of the antioxidant effect of the coenzyme on early PD patients (i.e., patients who did not require specific therapy) versus placebo showed a decrease in the treated patients' disability [17].

Black and green tea, due to high polyphenol concentration, exert an antioxidant effect and may have a neuroprotective and neuroregenerative effect in this disease, although clear evidence to support this assertion, derived from clinical research, is scarce [18].

Flavonoids enhance the endogenous activation of antioxidant enzymes, inhibit the peroxidation of lipids, and reduce the production of inflammatory mediators [19]. Due to all these actions, flavonoids exert a favorable effect on dopaminergic neurons and mitigate PD manifestations in laboratory studies [19].

An association between PD and a lack of adherence to the Mediterranean diet suggests a potential neuroprotective effect of this diet, through an undetermined mechanism that may attenuate the OxSt and inflammation, which are both recognized pathogenetic factors in PD [20].

Alzheimer's disease and small vessel disease

Alzheimer's disease (AD) is a neurodegenerative affliction characterized by the dysfunction of memory, attention, and other cognitive processes; it is the most common form of dementia [21]. Small vessel disease (SVD) may affect microvasculature systemically or mainly in the brain, the latter constituting a devastating cause of stroke and dementia worldwide [22,23].

Pathogenesis

AD mainly determines a synapse affliction, with the development of senile plaques mainly containing β-amyloid (Aβ). Aβ derives from the proteolysis of the amyloid precursor protein performed mainly by the enzymatic actions of β- and γ-secretase, with an imbalance between production and clearance causing the Aβ buildup [21]. The lesions produced by OxSt in AD are associated with an accumulation of Aβ [11]. Aβ buildup is also a central feature of the cerebral amyloid angiopathy form of SVD, to which AD is intimately connected; some might argue that the two constitute an inseparable spectrum [22]. The other form of SVD, deep perforator arteriolosclerosis, centrally features a blood-brain barrier (BBB) dysfunction, subsequent morphological and functional changes to the vascular wall, as well as myelin impairment [22,23].

Aβ determines the release of ROS by attacking mitochondrial enzymes (particularly cytochrome c oxidase), leading to mitochondrial dysfunction, increasing superoxide radicals, conversion to hydrogen peroxide (H2O2), the release of cytochrome, affecting the production of ATP and cellular apoptosis [21].

OxSt increases with aging and it is an important causal factor in the appearance of AD and other neurodegenerative age-related diseases, such as SVD. Moreover, OxSt is thought to bridge the connection between SVD and AD [24]. It is not yet fully understood how neurochemical factors influence the appearance of age-related cerebral lesions, but more and more data has shown the involvement of biometals (Cu, Fe, Zn) in Aβ accumulation. Copper is a potent mediator for the hydroxyl radical, and the high-affinity link between copper and Aβ (via histidine and tyrosine), as well as between zinc and the amyloid precursor protein and Aβ may contribute to the increased OxSt in AD [11].

Apolipoprotein E is a lipid transport molecule believed to be related to ROS and directly to lipid peroxidation in AD [25]. Carriers of apolipoprotein E4 more often have cerebral amyloid angiopathy [24].

To conclude, the involvement of OxSt in AD pathogenesis is supported by the high concentrations of Cu, Fe, Al, and Hg in the brain parenchyma, a high level of lipid peroxidation and DNA oxidation, as well as a decrease in polyunsaturated fatty acids, in cytochrome c oxidase activity, and energy metabolism [11]. OxSt could become a promising link between AD and SVD; therefore, research focusing on OxSt may decrease the neurological manifestations of both illnesses [24].

Nutrients

In preclinical research, caffeine has been associated with a tendency to lower the Aβ levels in early (familial) AD, because of its antioxidant properties [26]. Studies on cerebral amyloid angiopathy models are lacking.

Curcumin is an antioxidant and anti-inflammatory agent (inhibiting cyclooxygenase and lipoxygenase) that has been shown to reduce carbonyl derivatives, facilitating Aβ disaggregation, with possible beneficial effects in AD in animal studies [26]. Curcumin may also aid endothelial function, which is frequently impaired in SVD, as it has been shown to diminish the risk of stroke in animal models [27].

Vitamin E is a potent antioxidant that prevents oxidizing lesions induced by Aβ in cell cultures; it also delays memory impairment in animal studies on AD [28]. Some RCTs suggested vitamin E, through its antioxidant effects, may delay functional disability in patients with mild to moderate AD [29]. Vitamin E tocotrienols have demonstrated a positive impact on white matter lesions (associated with SVD) in an RCT [30].

Polyphenols (such as anthocyanins from berries, catechins and flavonoids from tea, curcumin from turmeric, and resveratrol from grapes) have an antioxidant effect with possibly associated neuroprotection, observed in preclinical models of AD [26]. Dizziness improved in SVD patients taking polyphenols [31].

The association between AD and a lack of adherence to the Mediterranean diet indicates that the latter may have a neuroprotective effect through an as-of-yet incompletely understood mechanism, potentially including an influence on OxSt and inflammation, both involved in AD pathogenesis [32]. Compliance with a Mediterranean diet lowered the burden of white matter lesions in SVD patients [33].

Due to their antioxidant properties, alkaloids such as groenlandicine, berberine, and palmatine from Coptis chinensis rhizomes may find their use in AD treatment [26]. Berberine promotes endothelial health and has been proven to support proper arterial elasticity in human subjects [34].

Milk thistle (Silybum marianum) diminishes OxSt and memory decline in laboratory studies of AD [35]. Milk thistle extracts also favored proper endothelial function in mice [36].

Ginkgo biloba, through its capacity to purge ROS, may reduce Aβ aggregation in AD, which is suggested by certain in vitro studies [26], but on the other hand, this theory has been contested in the literature [37]. Currently, there is little proof to support the routine use of Ginkgo biloba in AD patients [26]. Ginkgo extract had a beneficial yet limited effect on cognitively impaired mice models of SVD [38].

Melatonin overcomes apoptosis, prevents Aβ from interfering with mitochondrial DNA, diminishes lipid peroxidation, and, in high concentrations, protects from the OxSt induced by Aβ [39]. However, more studies are needed to prove its efficiency in delaying progression in early AD stages or in AD prevention [39]. Melatonin was shown to be a potential BBB integrity protector in cell cultures [40].

Coenzyme Q10 is an antioxidant factor that maintains mitochondrial membrane potential during OxSt, while also protecting neural cells from excessive Aβ deposition in laboratory studies of AD [26]. It also eliminates peroxyl radicals and may prove efficacious in AD [17].

Amyotrophic lateral sclerosis

Amyotrophic lateral sclerosis (ALS) is a progressive degenerative disease defined by a loss of central and peripheral motor neurons [41].

Pathogenesis

The pathophysiology of ALS onset is quite complex, probably heterogeneous, and not fully understood [42]. OxSt is a common link between various pathogenetic mechanisms of ALS, contributing to: (a) mitochondrial dysfunction: high ROS levels may augment mutations in mitochondrial DNA, and mutations of the Cu-Zn-SOD1 mitochondrial gene are synchronous with increased OxSt;(b) protein aggregation: OxSt is a contributor to the mechanisms of abnormal aggregation of SOD1; (c) axonal transport: certain fragments of axonal neurofilaments are targeted by OxSt [43].

Environmental or modifiable risk factors may be the source of OxSt, incriminated in ALS pathogenesis: (a) smoking induces lipid peroxidation, DNA damage, and cellular death, smokers having a higher risk of ALS (sporadic form); (b) chemicals used in agriculture (pesticides, organophosphates) are linked to ALS and induce mitochondrial dysfunction and ROS production [44].

It is not clear whether OxSt is the main cause of ALS or if it is a consequence of all the other pathogenetic mechanisms involved, but the existence of SOD1 gene mutation among familial cases suggests OxSt is central to the pathophysiology of genetic forms of ALS, at the very least [43].

OxSt could also interfere with ALS pathophysiology by deteriorating the mitochondria that support presynaptic transportation and, hence, affecting presynaptic mechanisms involved in neurotransmission [45]. ROS and reactive nitrogen species (RNS) alter RNA processing, generating mitochondrial dysfunction that eventually leads to neuronal death [46].

In ALS, indicators of OxSt are increased, such as carbonyl derivatives (in sporadic forms), 3-nitrotyrosine (a marker of oxidative lesions, with a higher expression in sporadic forms as well as familial forms associated with SOD1 mutation), 8-hydroxy-2'-deoxyguanosine (a sign of damaged DNA), 4-hydroxynonenal (showing lipid peroxidation) [43].

Nutrients

Laboratory studies have proven that mecasin (also known as KCHO-1, a herbal extract) diminishes OxSt via the gp91phox and MAPK pathways in ALS patients. Mecasin improved motor function and delayed ALS onset in study models [47].

EGb761, a standardized Gingko biloba extract with antioxidant and neuroprotective effects, could prove useful in treating ALS patients [48].

To prevent OxSt from interfering in ALS pathogenesis, various antioxidant agents have been tested, such as vitamin E and vitamin B complex; however, there were no significant proven benefits [43].

Multiple sclerosis

Multiple sclerosis (MS) is a chronic, inflammatory disease of the central nervous system [49,50], defined by perivenous lymphocytic infiltration and macrophage presence in the cerebral parenchyma [51].

Pathogenesis

MS neuropathology is characterized by focal demyelinating lesions and axonal lesions. Neurodegeneration is induced by inflammation and mitochondrial dysfunction, with ROS production as a common element. ROS promotes transendothelial migration of leukocytes, contributing to axon and oligodendrocyte degeneration [52].

ROS occurs mainly by the activation of macrophages, microglia, and astrocytes and are produced through NADPH-oxidase, myeloperoxidase, and inducible NO-synthase. ROS leads to neuron, axon, myelin, and oligodendrocyte destruction and may contribute to mitochondrial dysfunction, which in turn exacerbates ROS production, augmenting MS lesion appearance [52].

Through lipid, protein, and DNA oxidation, OxSt leads to cellular dysfunction and, finally, to necrosis or apoptosis [53]. In the early stages of MS, OxSt is associated with microglial activation and the inflammatory process, whereas in advanced stages, it is linked to mitochondrial dysfunction, pathological iron accumulation in cerebral structures and its release in demyelinating lesions [54]. Myelin and oligodendrocytes are the most damaged by OxSt in this disease, a phenomenon that has been supported by the cytoplasmic accumulation of oxidated lipids and nuclear DNA alterations [54].

Nutrients

Melatonin presents neuroprotective effects and may decrease the OxSt in individuals with secondary progressive MS [55] by ROS neutralization and induction of antioxidant enzymes [49].

Coenzyme Q10 potentially diminishes OxSt and stimulates the activity of antioxidant enzymes in relapsing-remitting MS [56].

Saffron extract attenuated OxSt in experimental studies on MS [57].

Vitamin D3 has antioxidant properties and has been shown to halt lipid peroxidation in MS literature [58].

Ischemic stroke and intracerebral hemorrhage

Ischemic stroke (IS) is the most widespread type of cerebrovascular affliction and a relevant cause of death and disability worldwide. Intracerebral hemorrhage (ICH) is about 30% of all non-traumatic strokes worldwide, with a higher disability rate compared to IS [59]. The major cause of ICH is small vessel disease, a complex microvascular affliction of the brain [23].

Pathogenesis

Normally, the BBB protects against neurotoxins. After ischemia occurs, various mediators of inflammation, as well as other potentially neurotoxic molecules, cross the altered BBB to the brain parenchyma, contributing to neuronal lesions [60]. A breakdown of the BBB also occurs in ICH, as well as an enhanced proinflammatory response with a release of ROS [61,62].

OxSt is an important factor involved in the pathophysiology of IS [63]. Immediately after a cerebral injury is produced in IS as a result of vascular obstruction, the rapid increase of ROS determines the extension of the ischemic area [64]. OxSt also occurs in ICH and may surprisingly have a disseminated impact, such as the induction of glomerular dysfunction [65].

The brain is particularly sensitive to oxidative lesions. The main sources of ROS in the brain are the mitochondrial respiratory chain, NADPH-oxidase (especially isoforms 2,3,4 that are notably expressed in the central nervous system) and xanthine oxidase (XO). Superoxide (O2−), physiologically produced by the mitochondria, is converted via SOD to H2O2 and acts as a cellular messenger, with a role in neuronal signaling in the central and peripheral nervous system. Oxygen depletion in ischemic neurons favors anaerobic glycolysis, with higher lactate levels and acidosis. The latter contributes to OxSt, providing H+ and hence facilitating O2− conversion to H2O2 [60].

After cerebrovascular flow is reestablished, the mitochondrial respiratory chain is reestablished with the generation of a new peak of ROS [63], contributing to cerebral reperfusion lesions [60]. O2− is involved in reperfusion lesions and NADPH-oxidase contributes to its production [60]. Mitochondrial malfunction has also been detected in ICH around the hematoma [66].

During cerebral ischemia, ATP is broken down to hypoxanthine, which accumulates in the ischemic cerebral parenchyma, and during the reperfusion phase, XO facilitates hypoxanthine oxidation to xanthine and subsequently to uric acid, a process during which O2− and H2O2 are generated [60].

An increase in excitotoxic amino acids such as glutamate in cerebral lesions as well as in the perihematoma region in ICH also favors the production of ROS [63,67].

Excessive ROS leads to lipid peroxidation and a deterioration of proteins and nucleic acids, hence the lesion area is extended and finally, necrosis and apoptosis occur [63]. Lipid peroxidation is the main pathway through which ROS impacts neurons: phospholipase A2 is activated by ROS and subsequently releases arachidonic acid, further enhancing the production of ROS. By impacting lipids, ROS produces aldehydes, dienals, and alkanes, thus provoking neuronal apoptosis. The process of DNA oxidation has an early onset in ischemia, and, although it is initially reversible, then an irreversible deterioration of DNA and cellular death appear due to all the ROS production pathways and a blockage of antioxidant mechanisms [60].

Nutrients

Vitamin C, playing the role of an oxygen donor, can revert oxidative processes [60]. Vitamin E is a lipid antioxidant capable of inhibiting lipid peroxidation and acting as a ROS scavenger [68]. In an experimental study, vitamin C and E administration diminished lipid peroxidation and IS volume [69], but their therapeutic effects were not proven in human observational studies [68,70,71]. Vitamin C plasma levels are reduced in ICH patients [72] and administering vitamin C and E in combination with ICH rat models had positive effects [73].

Coenzyme Q10 is a component of the mitochondrial transport chain, the latter being involved in ROS production [74]. Coenzyme Q10 builds up in the mitochondria, having a powerful antioxidant effect, proving its efficacy in neuronal protection in IS experimental models [75]. Coenzyme Q10 therapeutic strategies in ICH are also under investigation [76].

Citicoline is a natural component that may reduce the release of fatty acids during lipid peroxidation [74]. Citicoline has demonstrated protective effects in experimental IS studies [77], but these results were not obtained in IS patients [78]. Small double-blind trials on citicoline in ICH have shown an increase in muscular strength, however, this needs to be proven in larger studies [79].

Wormwood (Artemisia absinthium), a plant of the Asteraceae family, increases ROS purging and diminishes lipid peroxidation, managing to reduce IS volume in experimental literature [80]. Eupatilin, an Artemisia-derived flavone with antioxidant properties, had neuroprotective effects by reducing inflammation in the microglia in ICH cellular models [81].

Ginkgo biloba extract reduces lipid peroxidation and protects neurons against OxSt in experimental studies [82]. There is no convincing data to support its routine use in IS patients [83]. A systematic review on ginkgo biloba extract in ICH patients has recently shown promise for this therapy, but further validation is needed [84].

Gastrodia elata is a plant belonging to the Orchidaceae family with antioxidant activity, capable of inhibiting glutamate neurotoxicity [85]. In animal studies, it confers neuroprotection against cerebral lesions caused by ischemia and reperfusion [86].

In animal models, lavender oil proved to have antioxidant properties, reducing ROS levels in ischemic or reperfusion lesions [87].

Cannabinoids, mainly cannabidiol, have been associated with neuroprotective effects and the studies with rat cortical neuron cultures exposed to toxic levels of glutamate support a further investigation of these compounds in different pathologies, including ischemic stroke [88,89]. Also, cannabidiol is increasingly investigated in other disorders, including psychiatric illnesses, due to its anxiolytic, antidepressant, and antipsychotic properties, and the benefit of being administered as an adjuvant to current treatment, thus potentially decreasing the rate of treatment resistance [90,91].

CONCLUSION

To summarize, whereas it may play a variety of roles in the pathogenesis of various neurological diseases, oxidative stress is a worthy target to consider in future therapeutic strategies. Natural nutrients may have beneficial effects that can be impactful, pending more validation in the literature. Vitamin E appears as a versatile option, with potential neuroprotective effects in PD, a possible functional role in AD, and an antioxidant capacity in both ischemic and hemorrhagic stroke, although its clinical role requires further, solid proof. Coenzyme Q10 could also be useful to PD, AD, MS, and stroke patients, with a vast potential awaiting exploration. Ginkgo biloba might also hold promise in AD and stroke, but there is limited evidence to support its routine use, despite clinicians nowadays often adding it to therapeutic regimens. Pending improved technologies to refine and standardize natural extracts, as well as solid and validated methodology usage in RCTs, novel therapies may include nutrients in a plethora of neurological diseases.

GLOSSARY

Aβ = β-amyloid; AD = Alzheimer's disease; ALS = amyotrophic lateral sclerosis; ATP = adenosine triphosphate; BBB = blood-brain barrier; GPx = glutathione peroxidase; ICH = intracerebral hemorrhage; IS = ischemic stroke; MPTP = 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine; NADPH = nicotinamide adenine dinucleotide phosphate; OxSt = oxidative stress; PD = Parkinson's disease; RNS = reactive nitrogen species; ROS = reactive oxygen species; SOD = superoxide dismutase; SVD = small vessel disease; XO = xanthine oxidase.

Conflicts of interest and sources of funding

The authors declare no conflict of interest. No artificial intelligence automatically generated text was inserted in this manuscript, and no image was previously published in another journal or is under consideration of being published elsewhere. This research received no external funding.

INTRODUCTION

In the current military-political context, with the Cold War having ended (1947-1990), we find ourselves in full anti-terror war (since 2001), in which Romania is a direct participant, as a member of NATO and the EU, and the issue of biological warfare and bioterrorism is again highly topical but bearing other valences.

DEFINITIONS

War is a short or lasting conflict (whether military or not, declared or not), between two or more groups, social categories or countries, aiming to achieve financial, ethnic, territorial, economic and political interests.

The biological warfare is the artificial spread by various means of pathogens that can cause serious infectious and contagious diseases as well as the spread of germ toxins that can be used by an aggressor as a means of fighting in order to reduce the troops' fighting force, by causing serious disease outbreaks or by killing people, animals and/or plants.

Weapons of mass destruction (WMD) are those weapons, which, used by the aggressor, cause extensive material damage (destruction of buildings, constructions, machinery, installations, means of transport, etc.) as well as a large number of victims among employees and unprotected animals.

Chemical, biological, radiological and nuclear defence (CBRN defence) represents the protection measures taken during times of war or terrorist attacks, in the event of a chemical, biological or nuclear attack.

The biological weapon is a system of unconventional weapons of mass destruction, whose ammunition carries biological agents and contaminates the enemy in order to cause disease outbreaks for the latter.

Biological agents are microorganisms and/or microbial,

[1] The Military-Medical Institute, Bucharest, Romania

[3] Military Medical Research Center, Bucharest, Romania
[4] "Titu Maiorescu" University, Bucharest, Romania

animal or plant toxins, used as specific ammunition for biological weapons or used by terrorists in "bio-chem" attacks.

Total war is a large-scale conflict in which policy makers mobilize all available resources to ensure the destruction of the rivals' ability to defend itself. During times of total war, there are no actual non-combatants, meaning that all people in a particular country - civilians and military alike – are considered targets.

The hybrid war represents undeclared wars by those participating states, where the military component is not explicitly assumed and is by no means singular (they are executed in concert as part of a flexible strategy with long-term goals).

THE BIOLOGICAL ATTACK

Under the conditions of modern warfare, the effects of using the biological weapon can be amplified by successive or concurrent use with other WMDs. In a concrete battlefield, the biological attack can occur with:

a) The enemy on the offensive – can use the biological weapon to weaken the opponent's defence power. The most likely objectives to be attacked with biological agents would be:
1. Concentration of troops, resistance points
2. Reserve and support units
3. Air and sea troops found at bridge ends, traffic routes clogs, operational reserves, etc.

In the tactical and operative space, pathogens of diseases of short and virulent incubation, but non-transmissible from human to human, will be used. Infected animals or insects will not be used, as they would be dangerous for own troops.

In the strategic space, the aggressor will spread biological agents that cause many types of diseases to disrupt the battlefield, cause panic and aggravate material insurance.

b) The enemy on defence – could use the biological weapon against opposing troop concentrations to reduce their force of attack. Can be attacked with biological agents, the units in the offensive, those in the second line or the back-ups, the foreign military bases, etc.

In the operative space, infected insects and animals may also be used to target troop concentrations; the passes, roads, and crossing points may be contaminated to hinder the pursuit.

Living organisms are the sole targets of these attacks, thus buildings (for e.g.) being left intact, these being able to be decontaminated and further used. The biological agent is massively released into the area by the enemy and can contaminate a large number of humans and/or animals (anthroposoonosis) turning them into secondary sources of infection by releasing in their turn pathogens in the external environment. Except for those destined exclusively for humans and for those common to both humans and animals, there are also those biological agents destined exclusively for the destruction of domestic animals and cultivated plants.

THE PROVISIONS OF INTERNATIONAL LAW

From the point of view of International Law, biological weapons are expressely prohibited because they fall under the mass destruction weapons category, and their effect cannot be limited in time and space, with medium-term effects not always predictable. Moreover, the military use of biological weapons is currently considered to be tactically and operationally inefficient, being tactically difficult and risky from a medical point of view, because an outbreak once released can get out of hand.

Exceptions on using WMD

An important issue in controlling the Convention's implementation is the existence of certain exceptions because the Convention cannot completely ban the use of living agents and their toxins. So far, no convention banning the use of a certain type of weapon against the enemy has explicitly prohibited its use on its own population.

First of all, biological agents and some toxins can be used in vaccine manufacturing, for diagnostic and treatment purposes. For example, biological agents may be used in the treatment of inflammatory bowel diseases such as Crohn's disease inflammatory form with moderate or severe activity that have not responded to conventional immune-suppressive therapy or where immunosuppressant therapy is contraindicated. They may also be used in patients with moderate/severe RCUH who have not responded to corticosteroid and immunosuppressive therapy or severe/ fulminant colitis. These patients are required to undergo treatment with drugs such as Infliximab or Adalimumab containing a chimeric anti-TNFα agent consisting of IgG1 monoclonal antibodies, 25% murine and 75% human, respectively a fully humanized anti-TNFα agent, IgG1 type.

At the same time, the emergence of vaccines has greatly revolutionized medical science since they carry an important prophylactic role.

The vaccine is a biological product containing suspensions (antigens) of attenuated, inactivated (killed) viruses or living bacteria, or fractions thereof, which are administered in order to induce a specific immune response. Depending on the type of vaccine, fragments of pathogen agents were used differently:

1. Viral vaccines – corpuscular vaccines with living attenuated viruses (oral polio vaccine, rotavirus vaccine, measles, rubella, varicella, amaryllis) or inactivated viruses (inactivated polio vaccine, rabies, Hep A) and antigenic fragments or viral subunits (Hep B, influenza vaccine)

2. Bacterial-corpuscular vaccines with living attenua-ted germs (BCG) or killed (germs), (cholera vaccine, pertussis), polysaccharide subunits (meningococcal, pneumococcal, Hib, typhoid vaccine) or purified (pertussis acelular)

3. Anatoxin – diphtheria, tetanus

Thus, the BTWC allows all signatory countries to possess and use reasonably small (grams) quantities of BWA for defensive scientific research to obtain new means of diagnosis, prophylaxis and treatment. But a real problem is that these living biological agents can be multiplied on demand and in any quantity or can synthesize toxins as specific ammunition for biological weapons.

Secondly, one of the BTWC articles states that in case of force majeure, when a state itself is threatened, it may notify the UN three months before resuming the production of biological weapons to deter the enemy. This also explains why Israel, "an island in a sea of hostile Arabs", has not signed and ratified the convention.

And Romania, which joined since 1972, ratified it only in 1979, in order to have an extra advantage in the face of a possible assault of the USSR in the context after 1968. It should be underlined that in fact Romania has not researched, manufactured, stored, and has never used biological or toxin weapons, nor did it have such an intention, but it was indeed, the target of covert biological attacks in the 20th century and, we must continue to take preventive measures.

In this complex situation, effective legal measures for the application of the BTWC need to be implemented worldwide, but concrete actions are difficult to apply in practice. The UN is in a position, as an international forum, to impose and control compliance with the Convention, being helped by the Security Council, the World Health Organization as a specialized body.

STANAG are NATO standards for different areas that set technical or operational standards in certain situations, including in the field of biological warfare, and which need to be adapted and implemented by Allied countries for interoperability.

PREVENTION OF BIOTERRORISM ATTACKS

Preventing bioterrorist attacks is mainly a political and social problem, which is primarily achieved through the intervention of the secret services, police and the justice system. Combating bioterrorist attacks also involves the intervention of the National Health System, the National Defence System, etc. The specific capacities of the Medical Department of the Ministry of Defence are important for the medical protection against the weapons of mass destruction and especially for fighting against biological attacks, permanently having the forces and means necessary for the medical protection against the C.B.R.N agents.

The Center for Military Medicine Scientific Research (CCSMM) has a Laboratory of Anti-infective Medical Protection and Epidemiological Emergencies, which functions as a specialized medical protection unit against biological weapons. It conducts military medical scientific research to protect troops and the civilian population against biological weapons and/or toxins, for biological warfare events, bioterrorist attacks, or biological accidents targeting primarily: bacteria, viruses, fungi, etc. and their toxins, to establish medical protection procedures, through cooperation between different medical specialties: microbiology, epidemiology, etc.

A first stage subsequent to the occurrence of a biological attack is the identification of the causal agent, being performed solely in a microbiology laboratory, starting from correctly harvested samples (from the air, soil, water, pathological products from the sick, etc.). The identification operation must be quick and specific.

In the event of an immediate biological attack, the problem at hand is the immediate decontamination by appropriate physical and chemical means of the staff’s equipment, of the rooms, the water sources and the food, etc. The appropriate anti-epidemic measures to limit the spread of the infection are, along with the above, another important stage in the post-attack protocol, in which we will: isolate the sick and the suspects, take care of individual and collective hygiene, qarantine the D.D.D. actions and so on. If the agent has been identified, we can perform emergency immunoprophylaxis by using vaccines, by administering prophylactic or therapeutic antibiotics, etc.

The protection against biological attacks depends on the moment when the attack is detected, thus, when the media shall signal the imminence of an attack, the possibility to benefit from individual protection (ex-gas mask) and collective protective means (shelters) should be available. The biological means of protection and the emergency prophylaxis with appropriate substances (serums, vaccines, etc.) can be of good efficacy. Immunostimulators and chemo-therapeutic agents (wide-spectrum antimicrobials) can also be associated with these.

THE BIOLOGICAL WARFARE – A HISTORICAL REVIEW

There are very few data from the Prehistory and Antiquity that testify to the use of biological weapons during warfare. However, the latest research attests to the fact that the Hittites were the pioneers of bioterrorism. The Hittite people lived on a territory that today belongs mostly to Turkey. Three thousand years ago, they used infected sheep aiming at conquering enemy people. According to the study performed by the Italian microbiologist Siro Trevisanato, the bacterium considered the first weapon of mass destruction in history was Francisella Tularensis, responsible for tularemia, an infectious and contagious rodent disease, caused by a bacterium and transmitted to domestic animals and humans, manifesting itself by fever, chills, vomiting, etc. The disease still exists nowadays and, if not treated properly, can lead to death. Studying ancient papers, researchers have proven that tularemia first appeared in a Phoenician city (located on the border between Lebanon and Syria today) in the Middle East in the 14th century BC. The Hittites plundered this city in 1325, bringing with them infected animals, which may have spread the disease – also referred to as the "Hittite Plague" - throughout its territory, as explained by the researcher. Trevisanato points out that there are several papers attesting the epidemic. At the time of tularemia’s utter virulence, the Hittites came to the attention of a neighboring population of the city of Arzawa (Western Anatolia), who took advantage of their weakness to invade their territory.

During the Middle Age as a Mongol saw his comrades die of plague in the three years of the siege of Caffa's Black Sea city, founded by the Genovese, he had the brilliant idea of throwing corpses over the city walls. The Genoese left the city, but the plague spread across Europe.

In the Modern Age – the First World War brought a more sophisticated biological warfare, with the development of microbiology, many pathogens causing diseases could be identified that could then be cultivated in the laboratory. There are suspicions about the use of plague against Russian troops at St. Petersburg. Petersburg in 1915, about horses being infected in US ports for British and French armies.

In the Contemporary Age – extraordinary intelligence has been invested in the development and modernization of all categories of weapons. Each country classified biological programs at the highest level of secrecy; there is little evidence today about the details of the programs being carried out, with only little evidence on the existence of such programs in the current media. Specific anti-human, anti-animal and anti-plant programs have been developed, agents have been standardized for use as weapons, and insects have been studied for use as natural dispersion vectors.

PERSPECTIVES

The range of pathogens used as biological weapons is very wide, which gives rise to particular difficulties in the elaboration of the protection and treatment measures. Types of agents:

1. Bacteria: anthrax, plague, cholera etc;
2. Viruses: yellow fever, tick-borne encephalitis (TBE), smallpox, etc;
3. Rickettsia: Q fever, exanthema of typhus etc;
4. Pathogenic fungi: coccidioidoreo etiological agents, etc;
5. Toxins: bacterial (Botulinum, staphylococcal, etc.), fungal, of animals or plants (ricinotoxin).

These are only the pathogens found in nature. But new genetic techniques now allow us to obtain germs with new qualities, not naturally occurring (modified or hybridized) and which can be considered more dangerous by their pathogenic effect and increased resistance in the external environment.

Some agents have a lethal effect, while others have an incapacitating effect, leaving man out for a period of time ranging from a few hours to a few weeks.

They can be joined by immunosuppressive substances, which disrupt the mechanisms of the body's anti-infectious resistance, exposing it to current infections or to those deliberately disseminated.

In the case of a biological attack, it should be stressed that the possibility of using two or more biological agents simultaneously, whose effects combine or potentiate, or can be used with other weapons of mass destruction, is estimated.

We can also mention the existence of biological agents destined exclusively for destroying domestic animals and cultivated plants (e.g. avian influenza, barberry rust for plants) that can lead to large losses or can be used to destroy the economy of a competing country etc.

CONCLUSIONS

There is information that there are still laboratories and plants specializing in the research and manufacture of biological weapons. Most of the results of such research are not intended to be published; however, a number of research guidelines that testify to the trends in the improvement of biological weapons and their means of use can be deduced from the data published by researchers from several research institutes (e.g. the study of some of the most dangerous communicable diseases in humans and animals that currently have a very narrow spreading area). Another evidence of concern in the field of biological weapons is that the military personnel of some states are regularly exposed to prophylactic vaccines against some infectious diseases that are not circulating in the respective country.

We believe that the threats posed by bioterrorism are real and that it is mandatory to be prepared at any time to prevent, combat and liquidate the consequences of "bio-chem" attacks, respectively the management of the consequences.

REVIEW

The Transformative Role of Artificial Intelligence in the Future of Radiology

Dragoș Cuzino[1], **Adriana S. Capisizu**[1]

[1] Faculty of General Medicine, Carol Davila University of Medicine and Pharmacy, Bucharest, Romania

Correspondence: Adriana S. Capisizu, sorinacapisizu@yahoo.com

Abstract: Recent advances in technology and artificial intelligence have transformed radiology. Artificial intelligence, which uses machine learning, deep learning algorithms, and cellular neural networks, is now applicable to image analysis, enabling the analysis of large volumes of data and the early identification of lesion features, such as tumors. Integrating artificial intelligence into clinical workflows increases the efficiency of medical report generation and enables efficient prioritization of complex or urgent cases. Predictive analytics based on artificial intelligence uses extensive patient data, including demographics, medical history, tests, and imaging, to build more accurate predictive models. Among the areas where artificial intelligence is successfully implemented in radiology is the automated detection of lung nodules. In the field of neurology, artificial intelligence helps track progressive lesions through volumetric analysis of the brain and surveillance of demyelinating diseases. In oncologic radiology, artificial intelligence is used for automated image segmentation, lesion review, and standardized report generation. Therefore, in this ever-evolving landscape, radiologists must embrace emerging technological advances in order to occupy a unique position at the intersection of different diagnostic fields.

Keywords: artificial intelligence; radiology; magnetic resonance imaging; computed tomography

INTRODUCTION

The Current State of Radiology and Its Importance in Modern Medicine

Radiology has been closely linked to the degree of technological evolution and has experienced revolutionary developments in recent years. This review examines the implementation of Artificial Intelligence (AI) in radiology, examining its practical applications, associated challenges, and potential paths for progress.

Radiology is a medical field that, through several imaging technologies, including Magnetic Resonance Imaging (MRI), Computed Tomography (CT), Positron Emission Tomography (PET), ultrasound, and conventional radiology, contributes to the formation of medical diagnoses [1].

Challenges facing radiology today include a high workload that is not adapted to the existing workforce, corporatization, streamlining of workflow, and burnout. All of these contribute to the “perfect storm,” creating pressure on radiologists and the institutions in which they work [2].

In this context, AI can contribute to the evolution of radiology, from improving image acquisition to image interpretation with the help of advanced image analysis [1].

Understanding Terminology: AI, ML, and DL

Artificial intelligence has a contribution in radiology through machine learning (ML) and deep learning (DL) algorithms that play a role in image analysis.

Artificial intelligence is the replication of human intelligence in machines programmed to simulate human thought and action, with the aim of creating intelligent systems that operate autonomously and have the ability to solve problems that would normally require human intelligence.

Machine learning algorithms have emerged in recent years and are based on the introduction of decision trees, support vector machines, and neural networks, with these algorithms forming the basis of image analysis.

Deep learning is a subset of ML that uses multilayer artificial neural networks, which allow DL algorithms to understand complex data, which is successful in visual recognition. The layers are learned from the data, with architecture inspired by the human brain [1, 3].

HOW ARTIFICIAL INTELLIGENCE IS CHANGING THE FUTURE OF RADIOLOGY

AI is crucial to radiology's future in many aspects:

Intelligent image analysis algorithms

Through DL, AI can analyze large volumes of unstructured data, such as images, and learn patterns to automatically recognize features from the raw data. Through these technologies, and particularly through Convolutional Neural Networks (CNNs), AI has revolutionized the early identification of lesion patterns in CT scans [3].

Increased workflow speed

Integrating AI into clinical workflows gives radiologists quicker access to advanced imaging, speeding up results and helping prioritize complex or urgent cases [1]. There are areas where the use of artificial intelligence tools has reduced the workflow of radiologists by about 34%, such as in the case of breast cancer screening [4]. One of the main problems that arises when implementing AI in radiology is the lack of standardization between platforms and the fact that there are multiple AI tools with different user interfaces, which ultimately leads to an inefficient workflow, as radiologists must access different systems to reach the information provided by AI. The existence of a centralized AI platform, which integrates multiple diagnoses, with a single interface, can facilitate the workflow [5].

Predictions based on image analysis

The ability to make an accurate prediction of a patient's prognosis is essential for timely interventions. The emergence of predictive analytics through artificial intelligence allows the analysis of a large volume of patient data, including demographic data, medical history, and previous tests, which, together with imaging, can be used to establish predictive models with greater accuracy [6].

The role of AI in education

The current approach to education emphasizes a series of theoretical notions and a practical case-based experience. However, the method has its limitations, exposing learners to a limited number of cases compared to real-world work situations, as well as limited access to expert radiologists in certain fields. This is an area where AI can have a transformative impact through its ability to analyze large volumes of data and provide real-time feedback to complement the knowledge acquired through traditional education. Also, the existence of work platforms with simulations of real cases, connected to large databases, can increase the quality of training for students and residents [7].

Another transformative element is the inclusion of interdisciplinary education; radiologists must go beyond the traditional focus and have experience in fields such as genomics, pathology, laboratory medicine, oncology, molecular medicine, and immunology. Thus, the radiologist can understand the complex data that modern AI systems introduce into analysis to generate multimodal results. Radiologists occupy a unique position at the intersection of diverse diagnostic fields and play a central role in the diagnosis and care of patients, which is why their expertise in placing imaging data in an integrative clinical context is essential. Interdisciplinary collaboration is the way to ensure that radiologists are active users of artificial intelligence. Another area that can be improved is communication skills, an area in which the existence of structured reports also helps interdisciplinary communication and the transmission of clear conclusions [8].

Radiology training programs should prepare radiologists to understand artificial intelligence and to be able to make decisions under uncertainty without being influenced by cognitive biases, a situation that training in risk assessment and probabilistic reasoning helps to improve. This shift involves more than simply adapting the curriculum; it involves an integrative mindset focused on continuing education and an education that emphasizes interdisciplinary collaboration. These are the values that can help radiologists adapt to the complexity of the modern data they face [8].

AREAS WHERE AI IS SUCCESSFULLY INTEGRATED IN RADIOLOGY

Oncology

Correct interpretation of images, considering tumor heterogeneity and imaging characteristics, is a key factor in cancer diagnosis. By integrating AI into the oncology imaging workflow, multidimensional information about tumors can be extracted, which together can aid in tumor staging and stratification, molecular diagnosis, metastasis prediction and treatment response [9]. The main directions of focus for the inclusion of AI in oncology imaging include automatic image segmentation, lesion review, and the generation of standardized responses based on automated analysis. A significant aspect in oncology is the development of radiomics, but also the contribution of AI in radiotherapy.

Among the areas where artificial intelligence is successfully integrated into radiology is oncology, where techniques for automatic image segmentation, lesion review, generation of standardized responses based on automated analyses, and the development of radiomics have been successfully implemented.

Automated Image Segmentation

DL significantly contributes to image segmentation and classification and therefore increases the speed and accuracy of diagnosis. CNNs contribute significantly to the ability of artificial AI to learn complex patterns, which are found in fields with visual components, such as radiology. This is possible due to the complex, layered architecture of these networks, which have demonstrated increased ability in object detection and segmentation. CNNs have shown a key role in segmenting brain tumors in MRI examinations. Other applications where CNN segmentation has been successfully applied in radiology are the individualization of lung nodules, also distinguishing between benign and malignant tumors in mammography [1, 10, 11].

Review of lesions

Radiology exploits the most useful AI algorithms to automatically identify, locate, and recognize abnormalities found on medical images, whether they are tumors, fractures, or other types of injuries. Among these, DL and reinforcement learning help AI systems increase diagnostic accuracy, helping to halve the radiologist's workload and medical decision-making time. DL models can identify small lesions more easily through resolution enhancement techniques such as interpolation and super-resolution. To increase the performance of AI analysis algorithms in medical object detection, image pre-processing procedures are applied. Among the image preprocessing techniques used in artificial intelligence for object detection in radiology, there are some important ones, such as spatial resampling, intensity normalization, image registration, data augmentation, noise reduction, and segmentation. Data augmentation techniques include rotating, scaling, and flipping images to create larger data sets for use in AI models. Radiological applications of AI object detection apply to both tumors and other types of lesions in a wide range of examinations, including X-ray and CT scans, but one of the most innovative applications is CNN-based segmentation in MRI imaging [12].

Development of standardized reports based on automated analysis

The existence of structured reports in radiology improves workflow efficiency by faster generation of medical reports, especially when there are variable templates for various clinical aspects. The European Society of Radiology (ESR) emphasizes the need to use structured medical reports to streamline workflow and reduce the potential for errors. The use of structured reports that include a standardized list of issues reduces the risk of error by guiding the radiologist through a system of reviewing key points. At the same time, a structured approach ensures better communication between specialties and ultimately contributes to better patient care. With multiple AI tools, there is a risk that radiologists will be overwhelmed, but AI algorithms for rapid image analysis and standardized reporting can create consistency and make these disparate AI tools work together more effectively [5].

Radiomics

Among AI techniques, ML and radiomics involve extracting predefined features from radiological images through a data characterization algorithm. These features encompass various aspects of tumors, such as intensity-based measurements, shape characteristics, volume, heterogeneity, vascularity, and effect on surrounding structures. The entire process aims to increase diagnostic and predictive capabilities [1, 9].

Radiotherapy

Technological progress in diagnostic imaging has improved the efficiency of radiotherapy by introducing artificial intelligence software that optimizes the segmentation of tumors and organs at risk, prognostic assessment, treatment planning and optimization, thus saving considerable time for the radiation oncologist [13].

Lung nodule detection and classification

An advantage and a significant improvement of the workflow in radiology services appeared with the programs for automatic analysis and segmentation of pulmonary nodules [14]. These programs have become routine and are permanently attached to PACS systems, identifying, measuring dimensions, analyzing the structure, density and location of pulmonary nodules with dimensions between 3-30 mm [14].

There are also limitations in the automated analysis of pulmonary nodules, among which the most significant are the false identification of vascular trajectories as nodular hyperdensities, and other limits in identifying lesions in areas with ventilation disorders, with motion artifacts or with fibronodular sequelae. However, automated analysis programs are continuously improving and shortening the times for preparing medical reports, increasing work efficiency, and becoming working tools for the redistribution of highly qualified human resources in other directions where they are still irreplaceable [15].

Another useful contribution is the automated comparative analysis of the evolution of pulmonary nodule sizes, in accordance with the intervals specified by specialist guidelines, such as that of the Fleischner Society, an aspect that contributes to establishing the most appropriate therapeutic and follow-up conduct [16]. Automated analysis generates medical reports that enter patients' electronic records in parallel with the generation of a set of images with automatically marked lesions [15]. A concrete example in practice is that provided by CAD-type analyses in the identification of undetected tuberculous lesions.

Trauma with applications in military medicine

In imaging departments serving emergency rooms in civilian or military field hospitals, cerebral hemorrhagic lesions, or hemorrhages in any part of the body, represent the most common cause of post-traumatic death. Rapid recognition of hemorrhages and the most appropriate therapeutic interventions are of paramount importance. The role of AI systems using ML is to optimize diagnosis in these situations through algorithms that recognize hemorrhagic lesions and assess their risk potential through CT and FAST ultrasound methods [17]. These programs use semiological notions of lesion recognition, such as Language Models (LM) for automatic 3D labelling to recognize hemorrhage subtypes based on brain segmentation, midline deviation, mass effect, cerebral edema, and hyperdensity values. Diagnostic models in neurotraumatology utilize various emergency diagnoses, including hemorrhage, ischemia, cerebral infarction, space-occupying lesions, mass effect, hydrocephalus, and midline deviation. Neurotraumatology lesion recognition models based on imaging data obtained through radiography, computed tomography, and MRI can also be used for the rest of the body, through 3D anatomical segmentation, 2D CNNs software, and Recurrent Neural Network (RNN) [18].

Neurology

By using the Picture Archiving and Communication System (PACS) system, lesions with complex neurological substrates can be effectively detected and characterized through automatic algorithms that have entered routine analysis in some types of cerebral pathologies.

Automatic Cerebral Volumetry consists of an efficient automated analysis based on segmentation using the 3D T1 MPRAGE sequence. For reference, the images and measurement values are compared with those of a comparative database of patients from the same age groups for whom the brain volume is reported. Thus, this program provides cerebral volumetric assessment in case of suspected dementia, by evaluating the frontal, parietal and temporal lobes, and particularly the hippocampus. Brain volume assessment can also be extremely useful in multiple sclerosis and other degenerative diseases, such as Multiple Systemic Atrophy (MSA), Progressive Supranuclear Palsy (PSP), and Cortico-basal Degenerative Disease (CBD).

The program can also analyze the volume of specific brain areas such as the caudate nucleus, putamen, globus pallidus, cerebellar cortex, and midbrain [19].

The *Evaluation of Arterial Intracranial Vascular Lumen* uses a Time-of-flight (TOF) acquisition for analysis before being processed with the Maximum Intensity Projection (MIP) program. The analysis program is attached to the PACS system and generates a medical report that includes measurements and imaging of the identified lesions. In the case of intracranial aneurysms, it is estimated that 10-15% of them are underdiagnosed, and these automated analysis programs can improve the anomaly detection rate with an accuracy of almost 100% [20].

The *Characterization of a Demyelinating Lesion* is based on the analysis of 3D Fluid-Attenuated Inversion Recovery (FLAIR) sequences that highlight the location of the lesions. The analysis includes classification of the lesions using various reference systems, such as the McDonald and Fazekas criteria.

The program can generate a medical report that includes data on the location and size of the lesions, the presence of new lesions compared to previous examinations, and key illustrative images that are included in the report. Thus, this type of analysis can be extremely useful in all demyelinating diseases, including multiple sclerosis [20].

Brain tumor analysis allows for the automated assessment of tissue structures associated with tumor presence in entities with different anatomopathological substrates. Automated tumor lesion analysis is performed after intravenous administration of a contrast agent, which evaluates the behavior and uptake of the contrast. Automated lesion analysis is applied to highlight and differentiate various lesions and tissue components, which can be especially useful in the characterization of glioblastoma-type lesions, metastases and other tumor types, such as meningiomas. Also, complex data analysis allows for the possibility of integration into radiotherapy and neurosurgery programs [21].

Prostate

AI has become a commonly used tool for the diagnosis of prostate cancer, useful for both radiologists and urologists in multiparametric MRI examinations. The speed and efficiency of prostate cancer diagnosis and staging are among the greatest achievements for AI in prostate MRI evaluation [22].

Prostate cancer staging is performed using the PIRADS classification system and is integrated into the PACS system. The AI-generated medical report provides PIRADS classification, prostate volume, and detailed multiparametric analysis of prostate lesions, including nodule identification and categorization. In addition, when available, previous examinations can be evaluated comparatively. Medical reports also include appropriate graphical representations and dimensional assessments, as well as mapping of prostate lesions [22, 23].

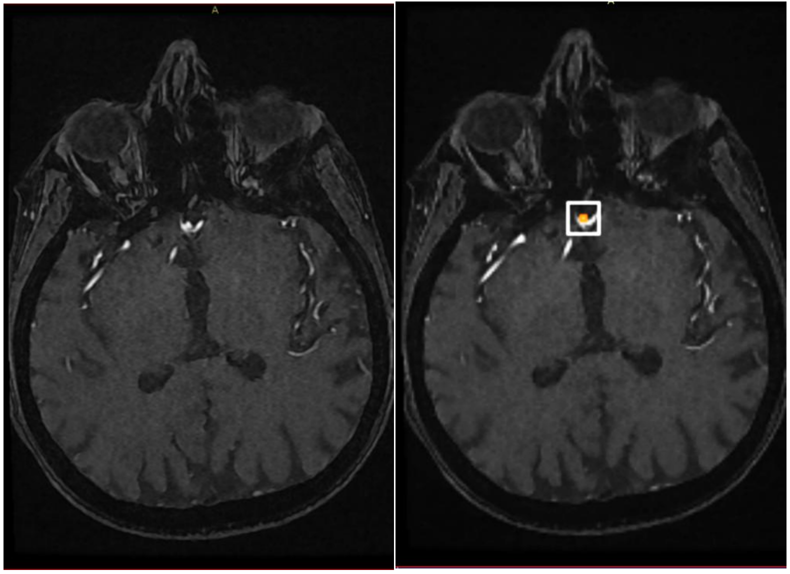
When the patient's PSA analysis is also available, this aspect can be represented in tables and associated with the presentation of prostatic density in the workflow report. This medical report can also be effectively used for image-guided biopsy, depending on the representation and arrangement of the most representative lesions [22, 23].

CLINICAL IMPLEMENTATION OF ARTIFICIAL INTELLIGENCE, CASE STUDIES AND APPLICATIONS

Case 1. Detection and analysis of intracerebral aneurysms using artificial intelligence

By analyzing brain MRI, TOF sequences, AI software can analyze the intracerebral vascular lumen and thus identify the presence of intracerebral arterial aneurysms and estimate their location and size (Figure 1).

Figure 1: Brain MRI examination. (A) Axial TOF images. (B) Automated detection of an aneurysm in the anterior communicating artery.

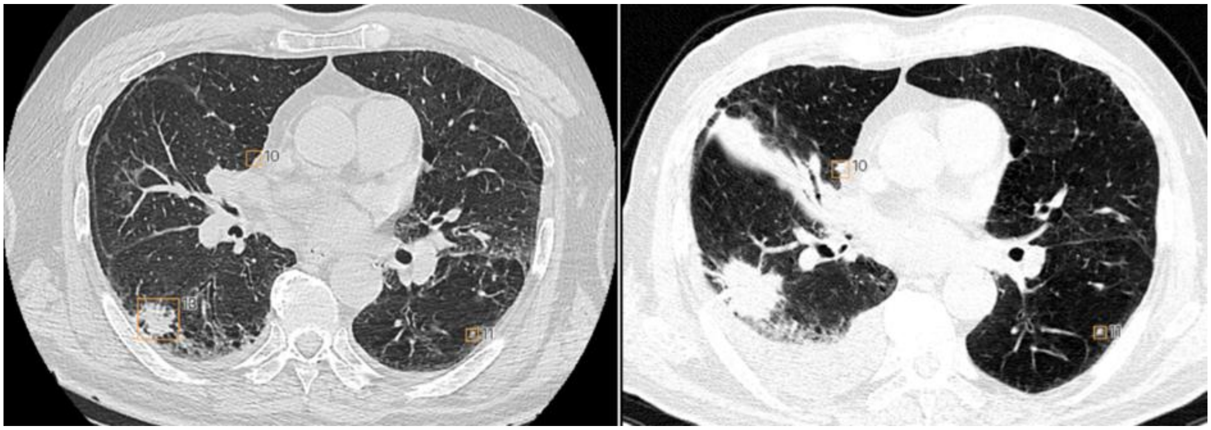


(A) **(B)**

Case 2. Automatic identification and dimensional monitoring of pulmonary nodular lesions

With the help of automated AI programs, in the case of thoracic CT examinations, the lung parenchyma can be analyzed for the presence of lesions, thus nodular lesions are identified, counted and measured automatically, and if there are previous examinations, the dimensional progression of the lesions can also be automatically assessed. Thus, with the help of AI tools, such as Rayscape, clinical impact improvement and shortening of diagnostic times are observed [24] (Figure 2).

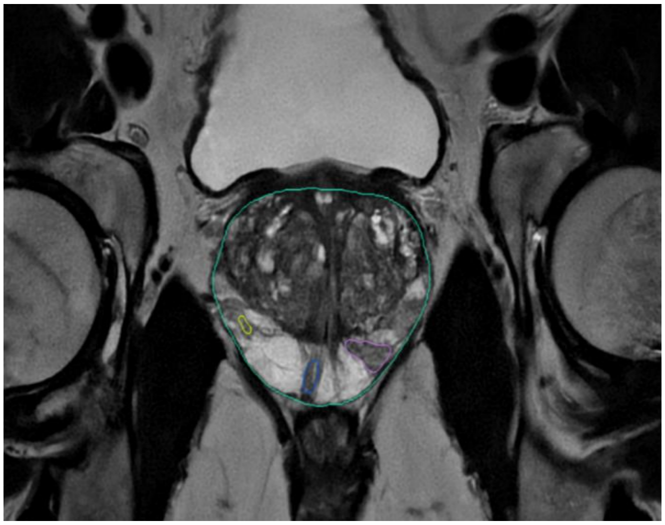
Figure 2. CT examination of axial sections, lung parenchyma window. (A) Automatic identification of pulmonary nodular lesions and dimensional assessment. (B) Automatic comparative analysis of pulmonary lesions with dimensional progression assessment.



Case 3. Automated prostate volume analysis and lesion characterization

Automated prostate analysis on MRI examinations is an area where AI has demonstrated progress and efficiency, so that prostate volume is assessed, lesions are identified, measured and classified according to PI-RADS classification, and a mapping of the most significant lesions is made in the report (Figure 3).

Figure 3. MRI examination, coronal T2 images of the prostate with automated prostate volume analysis and characterization of nodular lesions.



METHODS AND INDICATORS FOR EVALUATING THE EFFECTIVENESS OF AI PROGRAMS

The most useful evaluation method is the one that uses the Area Under the Curve (AUC) indicator in binary detection. The method is derived from the Receiver Operating Characteristic (ROC) curve, which uses sensitivity and specificity as parameters to state whether a lesion is present or not [17]. In the ideal mode, the optimal value of AUC is 1. Between 1 and 0.5 AUC has the appearance of a random model and below 0.5, it cannot be brought into discussion. At the current time, the interpretation in an efficient model has AUC values close to 0.9. The evaluation of the AUC indicator has, in turn, references and standards related to diagnosis established at the level of junior and senior radiologists with expertise. This level of over 0.9 is more easily achieved in lesions defined by few parameters and with clear values, such as hemorrhages, fractures, pneumothorax, lesions from mammographic examinations, while multiparametric defined lesions, such as prostatic or hepatic ones, require a senior radiologist-type standard of expertise. In the radiological evaluation of polytrauma in emergency services, high AUC values, above 0.9, and short processing time are required [25].

CONSIDERATIONS AND CHALLENGES

- Legal and ethical implications

The legal and social implications of artificial intelligence technologies in radiology need to be seriously assessed. One concern is the lack of transparency behind the decision-making process through artificial intelligence. Another key aspect in the implementation of artificial intelligence is the lack of a legislative system that regulates the level of involvement of artificial intelligence. Medical liability in case of malpractice is attributed to the radiologist. AI tools must meet rigorous validation and approval standards to establish their safety. Once approved, they must be continuously monitored to ensure that the results they provide are dependable. The implementation of AI systems requires adherence to established standards, appropriate regulatory approval, and awareness among radiologists and medical practitioners regarding their limitations, ensuring these factors are carefully considered [1, 26].

- Bias and generalization

Despite the development of artificial intelligence, when implemented in real life, its performance varies for certain subgroups. The question arises whether the goal should be fairness to the individual or fairness to the group. It has been observed that artificial intelligence takes shortcuts in the learning process, which can lead to biased results towards certain subgroups, for example, when multiple factors, including age, gender, and race, are taken into account in the diagnosis [27].

- Familiarization, incorporating AI into existing workflow systems

The integration of artificial intelligence into clinical radiology faces several challenges. One of these is the existence of robust hardware capable of managing the substantial amounts of data generated by medical imaging systems, which implies investment in such infrastructure. On the other hand, this new hardware and software must be able to integrate with existing radiology systems. There is also a need for training of radiologists and for them to collaborate with artificial intelligence developers [1].

A LOOK INTO THE FUTURE OF RADIOLOGY

The future transformation of radiology includes the integration of Augmented/Virtual Reality (AR/VR) and AI. AR/VR technologies are expected to play a significant role in radiological practice and radiological education by improving the visualization of radiological images, thereby contributing to diagnosis and treatment planning. Also, through machine learning, AI improves its image analysis capabilities, thereby contributing to reducing diagnostic errors. A tool based on AI is Computer-Aided-Diagnosis (CAD), which can contribute to the development of an integrative diagnosis by incorporating radiological, anatomopathological and genomic information into the AI-assisted workflow [1].

CONCLUSION

Artificial intelligence is developing rapidly, and understanding its use in medical practice is mandatory. Radiology is transforming, and specialists must keep up with it, adopting these innovative technologies and being integrated into multidisciplinary clinical teams, with collaboration between healthcare providers being paramount to fully capitalize on the benefits of this scientific knowledge.

Conflicts of interest and sources of funding

The authors declare no conflict of interest. This research work received no external funding. No AI tools were used to draft or edit the manuscript.

Abstract: Clinical research is the cornerstone of the progress recorded in psychiatry in the last six decades, or of what is called the psychopharmacological revolution. Regardless of the stage of clinical research, there are sensitive ethical and legal aspects that may appear during this process, and such challenges have to be acknowledged in order to preserve its scientific value, integrity, and centered-on-the-patient-wellbeing core principles. Also, adequate strategies focused on preventing the risk of ethical misconduct and litigation have to be found to avoid a loss of trust in the results of clinical research, to protect vulnerable populations from abuse, and to ensure a legally stable environment for investigators. In order to explore these practical problems, a narrative review was performed through a search in PubMed and Google Scholar databases. The main ethical risks detected in clinical research were related to errors in the methodology of obtaining informed consent, monitoring the participant's safety during the clinical trial, and falsifying collected data. Several famous cases of ethical misconduct were found and analyzed, and methods to decrease the risk of the re-appearance of such problems have been listed. In conclusion, this review is an invitation to explore the complexity of the methodology of clinical research and its ethical and legal risks, as well as to find new ways to mitigate the possibility of such risks related to the research process.

Keywords: clinical trial; volunteers; informed consent; vulnerable population; pharmacological agents; psychopharmacology; ethical misconduct

INTRODUCTION

Clinical research is an essential component of the broader paradigm of evidence-based medicine that is focused on ensuring scientific progress in healthcare. Although the evolution of medicine is an important objective, it must always be kept in mind when discussing clinical trials that the ultimate goal is to increase the quality of services offered to patients and improve their prognosis and chances of regaining a normal life. To refer only to the field of psychiatry, the developments recorded in the armamentarium of psychotropics in the last six decades represent a veritable revolution that allowed a change in the nosological paradigm of psychiatric disorders. Due to this change, which showed there is a biological basis for mental illnesses and that pharmacological agents can mitigate their symptoms, the stigmatization and the tendency to institutionalize patients with such diagnoses decreased and are expected to diminish further in the near future.

The importance of clinical research is illustrated by the high number of trials identified by a search in the International Clinical Trials Registry Platform (ICTRP), a World Health Organization database, that reported the existence of 10606 depression studies in 2024 [1]. According to the US National Library of Medicine database for clinical trials (ClinicalTrials.gov), more than 530000 studies are registered, out of which over 200000 are exploring a drug or a biological product, regardless of the pathology targeted, at the beginning of 2025 [2].

The need to conduct clinical trials in psychiatry is supported by a large number of practical difficulties when confronting the reality of mental health problems. One of the most critical challenges for clinicians is to increase the rate of responsiveness in treatment-resistant psychiatric illnesses, being known that 30-35% of depressive disorders, 30% of schizophrenia spectrum disorders, and up to 25% of bipolar disorders do not respond well enough to the usually administered pharmacological agents [3-7]. Another significant motive to foster clinical research in the field of psychiatry is the continuous quest to find new formulae to enhance therapeutic adherence (e.g., other ways of administration for a particular substance, coupling

the active drug with a vehicle that allows a slower release of the active substance so that the interval between administration could increase, or to find molecules with superior tolerability). Changes in the pharmacodynamic or pharmacokinetic properties of certain drugs that are already available for clinical use could lead to the discovery of new drugs with potentially superior properties. Covering emerging health needs, including mental health-related problems, such as the long COVID-19 syndrome, new psychoactive substances (NPS) use disorders, etc., is another important reason for conducting clinical trials.

Some of the above-mentioned directions of research have been more productive than others, while high expectations are related to the objectives insufficiently accomplished, like detecting pathogenic rather than symptomatic treatments or improving the tolerability of already existent drugs for treatment-resistant cases. For example, when discussing the improvement of treatment adherence, the discovery of long-acting antipsychotics that allow patients with schizophrenia to receive only two injections each year (i.e., paliperidone palmitate with 6-month release) could be considered significant progress [8-10]. The production of active metabolites as independent drugs, a process starting with tricyclic antidepressants, like nortriptyline from amitriptyline, or desipramine from imipramine, and continuing with new-generation antidepressants and atypical antipsychotics, like desvenlafaxine from venlafaxine, or paliperidone from risperidone, allowed for improving and diversification of pharmacokinetic and pharmacodynamic properties of the parent drugs [11-15]. Another direction of research is improving the pharmacodynamic properties of a racemic mixture by extracting only the most potent enantiomer, as was the case of escitalopram, levomilnacipran, or eszopiclone [16-20]. Even one of the most sensitive topics in psychopharmacology, i.e., the pathogenic vs. symptomatic treatments, acknowledged significant progress in the last years by the Food and Drug Administration (FDA) approval of monoclonal antibodies that target beta-amyloid peptides, like aducanumab, donanemab or lecanemab [20-23].

The responsibility for conducting clinical trials belongs to medical professionals, primarily doctors, but also to other categories of healthcare personnel – registered nurses, clinical psychologists, etc., who follow specific training programs before engaging in any research activity. Completing these training programs provides professionals with a common background of knowledge and skills necessary for participation in pharmacological studies. Specific certifications, such as Good Clinical Practice (GCP)– ICH Guidelines E6 R2, or qualifications for scoring scales and inventories used to measure the severity of clinical symptoms, have the aim to protect participants in clinical studies, reduce the risks of malpractice for investigators, increase the validity of data obtained from the research, and decrease the inter-rater variability of clinical scale results [24-27].

The Declaration of Helsinki regarding human experimentation originated in 1964 in the World Medical Association (WMA) statement and has been constantly revised ever since, with the last revision in 2024 [28-30]. This declaration is an essential step in the history of conducting research with human subjects, as it stipulates the fundamental principles of this domain, for example, the unconditioned respect for individuals and their right to self-determination and making informed decisions regarding their own health, including aspects pertaining to participation in clinical studies [28,30]. The primary duty of the investigators is to the patient or volunteer included in clinical studies, and the participant's well-being takes precedence over the interests of science and society [28-30]. This declaration also stipulates that ethical aspects are primordial and laws and regulations are only second in importance [28-30].

Ethical and legal errors in pharmacological research have the potential to harm not only study participants but also the integrity of the entire research process, thus indirectly affecting a very large number of patients who could benefit from a specific investigational product once it is approved. This narrative review is dedicated to highlighting the most relevant domains of clinical research that are vulnerable to malpractice risk and to investigate possible ways to decrease the probability of its onset.

MATERIALS AND METHODS

Two electronic databases (PubMed and Google Scholar) were searched for the terms „malpractice," OR „ethical issues," OR „methodological errors," OR „legal issues," AND „clinical trials," OR „pharmacological research," OR „drug research," OR „psychopharmacology." All primary and secondary reports published in English were selected if they corresponded to the inclusion criteria and did not meet the exclusion criteria. In order to ensure adequate coverage of this topic, grey literature was also searched for papers published in English. The period chosen for published papers was between the inception of each database and January 2025. Inclusion criteria: all types of research and commentaries, press releases and related sources of information; all stages of clinical trials, if related to the field of psychiatry; pharmacological interventions, either alone or in combination with other interventions. Exclusion criteria: non-pharmacological interventions used alone; reports that did not contain precise data on ethical or legal issues related to clinical trials in psychiatry; undefined outcomes or imprecise source of the referenced studies.

RESULTS

From the clinical research perspective, ethical and legal error problems appear when a doctor participating in clinical trials (hereinafter referred to as "investigator") does not comply with the correct way of obtaining adequate informed consent, mismanages patient safety measures, or falsifies research data. These actions can lead to serious consequences for participants, undermine the validity of clinical trial results, and negatively impact the medical community and society as a whole through the decrease of individuals' chances of getting the optimal cure.

Ethical and legal challenges related to obtaining informed consent

Signing informed consent is the first procedure a participant in a clinical trial has to perform prior to any study-related procedures [31]. This step is mandatory in the era of clinical trials conducted under rigorous ethical principles, according to the principles of the

Declaration of Helsinki [28-30]. The procedure of informed signed consent is mentioned in the GCP guidelines and reflects the principles of absolute respect for patients' autonomy and their right to be informed in every aspect of the trial that is relevant to their own health [24-27]. Also, the Declaration of Helsinki stipulates that whenever the participants are unable to give their own consent, surrogate consent may be obtained from an individual acting in the participant's best interest, but the consent of the participant still needs to be obtained if at all possible [28-30,32]. The cases when this procedure is applicable are also presented in the Declaration of Helsinki [28]. The investigator must ensure that this consent is given freely, without any form of coercion, and with a comprehensive understanding of the implications of the study [28].

Possible errors in this domain, which are compatible with a risk of malpractice, are (a) a failure to disclose potential risks of the trial, (b) providing false or intentionally incomplete information, and (c) coercing patients to participate in the study.

For example, if an investigator conducting a study fails to properly explain to participants the adverse events or health risks of the investigational product, patients could be exposed to a danger to their health that they did not voluntarily assume in the very beginning. A study exploring the proportion of participants in clinical trials (N=135 cohorts) who were aware of the different elements of informed consent showed that only 52-75.8% understood what they were signing [33]. According to this study, 74% of the participants were aware of potential benefits and less than 70% of the study's aim, while 66% understood the rule of confidentiality [33]. Also, the proportion of participants who understood the informed consent did not increase during the 30 years of the studies included in the review [33]. These data indicate the need for better communication between investigators and participants during the signing of the informed consent form.

According to the GCP-ICH, both the informed consent discussion and the written informed consent form and any other written information to be provided to subjects should include explanations of the testing hypothesis process involved by the clinical trial, which is the purpose of the trial, understanding the fact that the treatment is not validated and what is the probability of random assignment to each treatment/placebo [24-27]. Also, the participant must receive adequate information about the study procedures to be followed, including all invasive procedures, which are his/her responsibilities, those aspects of the trial that are experimental, and the reasonable risks that can be anticipated or inconveniences to the subject and, also, the reasonably expected benefits [24-27]. Other elements included in the informed consent, according to the same source, refer to the alternative procedure(s) or treatment(s) that may be available to the subject, and their potential significant benefits and risks, the compensation and/or treatment available to the subject in the event of study-related harm, and the anticipated payment, if any, to the subject for participation in the study [24-27]. The list of all elements that constitute an informed consent form is too extensive to be reproduced here, but this complexity explains the long time necessary for the investigator to explain the totality of the relevant aspects to each participant in order to obtain his/her approval to participate in the trial.

Patient safety and monitoring of adverse events

Investigators are responsible for carefully monitoring the psychobiological parameters of each participant in a trial, ensuring that subjects are not exposed to avoidable health risks [24-27]. This process presumes a regular verification for the existence of adverse reactions, offering adequate interventions if these appear and discontinuing participants' involvement if they develop a serious adverse event. Failure to comply with this principle is a severe form of malpractice and a clear violation of the core principles of the Declaration of Helsinki [28-30].

For example, if an investigator continues to administer an investigational product to a patient despite clear signs suggesting the onset of severe side effects, he or she is engaging in a form of negligence that can have severe legal consequences far beyond the violations of ethical conduct. In this area are placed the cases when participants who remain pregnant during the clinical trials are still receiving the investigational product or when adverse events to the experimental drugs are treated with medications not allowed by the study protocol, thus disregarding the potential of pharmacologically dangerous interactions. According to a study [34] focused on the understanding of potential trial participants regarding the monitoring and communication of serious adverse events during a clinical trial, it was observed that their awareness of safeguards or regulations in this domain was very scarce; also, many of them expressed the desire to be more informed about the potentially serious adverse events and short reporting deadlines. The same study reported on the concerns of participants about potential financial conflicts of interest in monitoring and further reporting serious adverse events during a clinical trial [34].

In the same direction, the 2024 revision of the Declaration of Helsinki notes that unproven interventions focused on alleviating pain or suffering must not bypass ethical safety measures or avoid evaluation by controlled clinical trials [35], highlighting the importance of conducting an accurate assessment of all health parameters even in the most severe patients.

New tools have been suggested for the most accurate monitoring of safety in clinical trials, including those using graphical visualizations that are congruent with the FDA/EMA (European Medicines Agency) guidelines [36]. Such tools are interactive and support regular medical monitoring and oversight [36]. The National Institutes of Health in the US require data and safety monitoring boards for all phase III clinical trials, which are conceived as a supplementary barrier to errors in safety monitoring [37].

Data falsification and breaking the research integrity

The accuracy of data collection in the clinical research process and the integrity of the analysis of information regarding the efficacy and tolerability of the investigational product are essential to provide valid results. Ethical breaks and legal issues can be detected in this field when an investigator manipulates or falsifies clinical data to obtain some desired results [38,39]. Data falsification exerts significant prejudice on the validity of research, endangers the patient’s safety, and violates the core ethical principles of medicine.

For example, such an unethical approach can lead to the approval by competent institutions of harmful or ineffective treatments for clinical use, which can significantly endanger future patients [38-41]. Furthermore, new research could be based on a false presumption, and this could exponentially amplify the negative economic and medical consequences of a single false study [38-41].

Several examples of data falsification and research integrity break are: (a) selective reporting, which is a form of reporting only data that supports the drug's efficacy while omitting negative or inconclusive results; (b) data harvesting, a phenomenon that refers to the selective analysis of certain variables that fit a desired outcome, ignoring others; (c) partial monitoring of tolerability data, which may be observed when there is a lack of monitoring or inadequate reporting of adverse effects that occur during the study; (d) lack of adequate monitoring of participants after the study ends to confirm that the investigator ensures that any long-term effects of the drug are documented and managed appropriately; (e) underestimation of risks, which refers to the situation when the investigators minimize or ignore potential risks that expose participants to short, medium, and long-term negative effects [38-43].

Another example of phenomena that negatively interact with research integrity is the participation in clinical trials of investigators with insufficient experience or without enough credentials, and this is a direct violation of the Declaration of Helsinki [28-30]. Thus, allowing individuals without the necessary certifications or knowledge to conduct or supervise critical aspects of a trial is an example of ethical misconduct [28-30]. Failure to provide adequate training to staff on ethical practices, safety protocols, or specific clinical trial procedures is also a breach of research integrity [28-30].

Ethical integrity can also be breached by improper recruitment and enrollment of participants [28-30,38]. For example, the inclusion of ineligible participants might refer to the enrollment of individuals who do not meet the inclusion criteria for the study, such as those with contraindicated health conditions or who are already taking other medications prohibited by the study protocol. On the other hand, but in the same category of ethical breaches, the exclusion of eligible participants refers to discrimination against specific populations, such as vulnerable groups, in order to distort results or save time. Such examples are the inclusion of participants diagnosed with major depression and active suicide ideation, although the study protocol prohibits their enrollment, and, on the other hand, exclusion of patients with severe depression due to the investigator’s fear they will be challenging to manage, although the study protocol allows their participation.

Ethical breaches may be derived from protocol deviations and protocol violations [44,45]. The first case refers to divergences between the study activities from the institutional review board (IRB)-approved protocol with minimal impact, while the second refers to divergences that reduce the quality or completeness of the data, inaccuracies in the informed consent form, or endanger the subject's safety, rights, or welfare [45]. For example, if the test procedures are modified or the treatment administration algorithm is changed during the trial without a clear rationale, these may affect the results and induce harmful reactions in the participants. Also, failure to adequately document protocol changes or deviations makes it impossible to assess their potential impact on the trial. Failure to report or address ethical concerns is a significant methodological and ethical or legal error that can be observed, for example, when an ethical review is neglected by failing to obtain approval from an IRB or ethics committee before the trial begins or failing to address ethical concerns raised during the review process [46].

Several ways to decrease the risk of protocol deviations are enhanced training for the investigators, regular monitoring visits, involvement of the Ethics committee in site monitoring, etc. [44]. In a study that explored 80 postgraduate dissertations, representing observational studies (74%) and interventional trials (10%), a significant proportion of protocol deviations (more than 42%) were due to nonreporting and incomplete documentation of the divergencies [47].

Consequences of malpractice in clinical trials

Clinical trial litigation has been rapidly escalating during the last decades, and defendants are not only principal investigators or sponsors but also IRBs, individual IRB members, study coordinators, etc. [48,49]. Beyond the legal repercussions, malpractice in clinical trials can have long-lasting effects on public opinion about medical research. Patients may become hesitant to participate in future clinical trials, fearing that their health may be at risk. As a consequence, the interest of the general public in research could decrease, and thus, the availability of new treatments for various disorders could be delayed, or potentially valuable drugs may even be abandoned.

Furthermore, the reputation of healthcare practitioners can be significantly damaged when cases of malpractice in clinical trials are discovered and exploited by mass media [50,51]. Such phenomena can fuel an environment of skepticism and mistrust, leading to the erosion of the relationship between the patient and the healthcare specialists. The impact is, consequently, negative not only at an individual level but also at a macro-social level, with consequences beyond the level of a research site or a certain clinical trial.

Examples of famous cases when ethical and legal violations of clinical research were detected

One of the first cases of ethical misconduct after the Nuremberg Trials, which brought to the general interest the dangers of experiments without ethical restraints, was related to the MKUltra studies (1955–1967) [52,53]. These involved „mind-control” techniques using LSD-25, and were sponsored by the CIA [52]. Many of the subjects were given LSD and other psychoactive substances without consent, and some were subjected to psychological manipulation; also, not all of the „investigators” were healthcare specialists, but they came from very diverse professional backgrounds, e.g., one of them was a magician, i.e., a student of Harry Houdini, while another was a CIA consultant with a shady history; tragically, this so-called experiment for mental illnesses became medical torture not very unlikely to the Nuremberg Trials [52,53]. Different reports describe the effects of these experiments on mental health, including the Veterans Health Initiative Report in 2003 [53].

The study 329 (1994–2001) investigated the use of paroxetine and imipramine in adolescents, and this research was later found to have serious ethical and scientific flaws, including selective reporting of results [54,55]. An independent reanalysis of the data from Study 329 (the RIAT initiative) showed that acute and long-term paroxetine and imipramine were harmful and ineffective in adolescents with major depression [54]. In the original study, paroxetine proved itself well-tolerated and effective in that population on multiple outcomes, i.e., the Hamilton Depression Rating Scale (HAMD), Schedule for Affective Disorders and Schizophrenia for Adolescents-Lifetime version (K-SADS-L), and Clinical Global Impression (CGI), while the withdrawal rates due to adverse events were 9.7% vs. 6.9% (paroxetine vs. placebo) [55]. The RIAT analysis presented several ways in which the presentation of safety data in clinical trials may influence the apparent tolerability of a drug, e.g., the use of an idiosyncratic coding system, failure to transcribe all adverse events from clinical records to an adverse event database, or filtering data on adverse events through statistical techniques [55]. This case is interesting because it represents an argument to make it available for independent analysis of all primary data available from a clinical trial [56].

The Ranbaxy Case (2006-2008) involved a major Indian pharmaceutical company in a significant controversy related to drug safety, more specifically to the quality of various generic drug products, including gabapentin and the antibiotic ciprofloxacin [57]. Ranbaxy was accused of falsifying data in clinical trials, including trials of generic drugs, related to the purity, strength and quality of these generics, and the case resulted in the company being fined $500 million by the US Department of Justice for selling counterfeit drugs and submitting false data to the FDA [57]. Incomplete testing records and inadequate programs focused on the assessment of the stability characteristics of drugs were detected by an FDA inspection in the Paonta Sahib facility in 2006 [57].

Other doubts about the regulation authorities failing to keep up with ethical issues in clinical research in India have been raised [58]. Although most of the alleged ethical violations were not confirmed, the controversy about the clinical trials in India has decreased dramatically the trust in clinical research originated in India [58]. Lack of informed consent from volunteers, conflict of interests surrounding the members of independent ethics committees, suspicions about the use of vulnerable populations, and lack of insurance or compensation in case of serious adverse events were subjects presented by activists [58]. In 2017, a guideline passed by the Indian Council of Medical Research was launched to improve the quality of clinical research in that country [59]. These guidelines approach sensitive topics, like the procedure to obtain informed consent, the respect for voluntariness, the definition of vulnerable population, the assessment of the benefits vs. risks balance, and the compensation for harm derived from participation in clinical trials [59]. Also, regularization of the Ethical Committee structure and functions are included in these revised guidelines [59].

Prevention of malpractice in clinical trials

The complexity of clinical research has attracted numerous debates over the last decades, and national institutions with responsibilities in the field of drug regulation have initiated their own rules and norms, besides international or regional ones. EMA, WHO (World Health Organisation), and WMA are the leading institutions with expertise in the regularization of clinical research [60-65]. National agencies, like the FDA in the US or the PMDA (Pharmaceuticals and Medical Devices Agency) in Japan, are also regulatory organizations with rich experience and ethical guidelines dedicated to clinical research [66,67].

In order to decrease the risk of ethical misconduct and litigations in this field, such institutions with responsibilities in the domain of monitoring the research activity must provide continuing education and training to physicians involved in clinical trials, ensuring that they understand the ethical, legal, and scientific responsibilities they bear. The activity of pharmacovigilance is also a topic that needs to be regularized because this stage is essential for ensuring post-marketing feedback from the patients. Phase IV studies are not at all less important than other clinical trials due to their importance in maintaining clinical use of only those drugs that prove themselves useful and tolerable, even after they pass the pivotal trials. The real safety profile of a certain drug may be defined only by continuing surveillance, and this requires an intense effort from patients, doctors, and regulatory institutions [68].

There is a need for effective oversight mechanisms, including local ethics committees, which evaluate the ethical, methodological, and safety aspects of clinical trials before and during their implementation. These committees act as a core protection for human research participants due to their independent review of the ethical acceptability or proposal for human research [69]. The importance of these organisms has been mentioned in the previous chapter, as avoidance of the conflict of interest within IRBs/Ethical Committees was a topic raised in the controversy surrounding clinical research in India [59].

Also, the transparency of research data implies compliance with rigorous protocols, with clear documentation of all procedures, decisions and results, which can be audited at any time by competent national and international institutions. This aspect's importance was highlighted by the Study 329 case, where an independent re-analysis of the original data provided different results [54].

DISCUSSION

The progress recorded in the treatment of psychiatric disorders in the last six decades could not be possible without clinical research based on the dedication of the investigators and volunteers who contributed in a significant way to this endeavor. Like any scientific domain, clinical research is not free of ethical and legal challenges, especially because, due to its sensitive nature, it mixes epistemological aspects (i.e., the experimental nature of the investigational process), with axiological (i.e., the liberty of the individual as a core value), and ontological ones (e.g., the biological vs. spiritual causation of our mental life). Thus, hypersensitive topics are related to each dimension; starting from the acknowledgment of the participants that they assume certain health risks in a clinical trial, continuing with the voluntariness vs. coercion dilemma when being recruited for a study, or with the liberty to decide when to withdraw from a trial, all these aspects may be negatively exploited and consequently may trigger ethical misconduct and litigation. Clinical research has received a lot of attention from both the scientific world and the public, not to mention the vehicle between the two, i.e., the media. Avoiding dogmatic thinking and understanding the complexity of clinical research is important for any investigator, as is the ability of scientists to maintain the transparency of the research to society, which is the final beneficiary of their work. The legislation in the field of clinical trials is an evolving organism, and the Declaration of Helsinki is the result of the conjugated effort of society and the scientists trying to prevent the repeating of tragic ethical misconduct as in the Nuremberg Trials, MK Ultra experiments, etc.

Because the number of clinical trials is continuously increasing as a result of the social pressure to find more performant and more tolerable pharmacological agents, not to mention the need to respond to newer threats to human health, there is an ever-higher need to control the potential risk factors for ethical deviations in clinical research. Therefore, the vulnerabilities related to the clinical research methodology explored in this review, i.e., those about the obtaining of informed consent, those connected to patients' safety, and those derived from data falsification, need to be continuously monitored and regulated by authorized institutions. The failure to do so would lead to a decrease of public trust in clinical research and virtually erase the line between scientific, validated-through-trials pharmacological agents and any other substance promoted by non-regularized commercial entities. This is a very important and actual topic because psychedelics (LSD included) or other substances with a risk of addiction are nowadays explored again for the use of various mental disorders, while various therapies with innovative mechanisms (e.g., focused on immune factors or gene modulation) are also emerging as potential solutions for multiple, psychiatric or somatic, illnesses [70-75]. Therefore, a continuous updating of ethical guidelines is needed to protect the participants in clinical trials from any type of abuse and to allow the investigators to work in a legally secure environment.

CONCLUSION

Pharmacological research activity is an essential component of the approach aimed at increasing the quality of medical practice by multiplying the existing therapeutic options for a specific medical condition. Evolution in the field of medicine is impossible to achieve, at least taking into consideration the current level of scientific knowledge, without clinical trials. Through this type of activity, progress in pharmacology is ensured, and the quality of patients' lives is increased while their chances of functional recovery and prognosis are improved.

Ethical and legal risks in clinical research derive mainly (but in no way exclusively) from (1) irregularities in obtaining informed consent of participants in the study, (2) failure of investigators to respect the safety of participants in the clinical study, and (3) incorrect reporting of data obtained from the research.

Controlling these risks involves respecting the stages of professional training of clinical trial investigators, as well as the efficient functioning of institutional control mechanisms in the field of pharmacological research.

Conflicts of interest and sources of funding

The authors declare no conflict of interest. No artificial intelligence automatically generated text was inserted in this manuscript, and no image was previously published in another journal or is under consideration of being published elsewhere. This research received no external funding.

Abstract: The Human Immunodeficiency Virus (HIV) and the Acquired Immunodeficiency Syndrome (AIDS) remain significant public health concerns worldwide. This review seeks to present an updated perspective on the spread, consequences, and control measures of HIV/AIDS, focusing on military personnel as a particular at-risk group. It starts by outlining general information about the transmission of the virus and summarizing recent global epidemiological trends. This review further explores the difficulties that HIV/AIDS presents in military settings, including policies regarding the management of service members living with the virus. Additionally, it examines several prevention strategies implemented by militaries around the world, such as educational programs, provision of condoms, and efforts to reduce the stigma associated with the infection.

Keywords: HIV; AIDS; military population; prevention; treatment; management

INTRODUCTION

The Human Immunodeficiency Virus (HIV) was first presented in 1983 as a non-transforming retrovirus [1]. This virus targets CD4+ T lymphocytes and is responsible for Acquired Immunodeficiency Syndrome (AIDS) in individuals with the infection [2]. This condition is characterized by two human lentiviruses: HIV-1 and HIV-2, with transmission occurring exclusively from human to human. Typically, in the absence of a treatment, HIV-1 infection can lead to AIDS, a syndrome associated with significant mortality rates [3]. Both HIV-1 and HIV-2 are RNA viruses that carry the necessary information for the synthesis of the viral proteins essential for the replication and assembly of the virus [4].

HIV transmission occurs either horizontally or vertically [5]. Vertical transmission is the most common way for children to acquire the infection, either in utero, during childbirth, or through breastfeeding [5,6]. Horizontal transmission involves needle sharing or unprotected sexual contact [5,7,8].

One population that has been identified as vulnerable to acquiring HIV infection is military personnel, due to frequently reported high-risk sexual behaviour [9,10] or to their high mobility and exposure to biologically foreign environments [11,12].

Aim

This literature review explores the challenges faced by military populations in the context of HIV/AIDS and presents prevention strategies and proposed solutions for effective prevention and control in this high-risk group.

MATERIALS AND METHODS

This paper examines the medical literature concerning HIV/AIDS, as well as the public information disseminated by state agencies regarding programs and strategies aimed at preventing HIV transmission among military personnel.

RESULTS

HIV/AIDS: General Overview and Key Statistics

At the end of 2022, the World Health Organization reported that 39 million people were living with HIV, including 1.5 million children. That year, 1.3 million people contracted the virus, reflecting a 38% decline compared to 2010, when 2.1 million new cases were reported [13].

Concerning HIV-related mortality, 2022 saw 630,000 deaths attributed to the virus, down from an estimated 1.3 million deaths in 2010. This represents a 51% decrease over a 13-year period.

In terms of treatment, around 29.8 million people received antiretroviral therapy (ART) in 2022. Among those infected that year, 86% were aware of their HIV status, 76% had begun treatment, and 71% had successfully achieved viral suppression [13].

The African continent remains the most affected globally by HIV, with an estimated 25.6 million individuals living with the virus. Within this group, 90% are aware of their status, 82% receive antiretroviral therapy (ART), and 76% have achieved suppressed viral loads. The region has also seen a significant drop in incidence per 1,000 uninfected individuals. Along with a 56% decrease in AIDS-related deaths since 2010, down to an estimated 380,000 annually [13].

The European Region has an estimated 3 million people living with HIV. Of these, 72% know of their status, 63% are undergoing treatment, and 60% have achieved suppressed viral loads. Roughly 1.9 million individuals are on ART. However, Europe has experienced a rise in HIV incidence over the past decade, from 0.16 to 0.20 per 1,000 uninfected people, alongside approximately 180,000 new infections reported in 2022. AIDS-related mortality has also increased by 37% since 2010, with an estimated 52,000 deaths recorded in 2022 [13].

In Romania, according to the latest data, 716 people were diagnosed with HIV/AIDS in 2023. Over the period from 1985 to 2023, a total of 18,389 individuals have been recorded as having the disease, with 8,556 losing their lives due to HIV-related causes [14].

Epidemiology of HIV in Military Populations

Military populations represent a unique demographic in the global HIV epidemic [11,12], being predominantly composed of young adults [15,16] and often deployed to environments where risk behaviors may increase - factors shown to contribute to new infections among U.S. Army Soldiers [17].

HIV incidence differs substantially across regions, with particularly high rates observed in certain areas of sub-Saharan Africa and Southeast Asia. In the United States, while overall HIV prevalence is lower, military personnel are not exempt. Despite strict screening protocols, they are not exempt [18]. As of March 2021, over 170,000 U.S. service members were deployed globally, marking the largest international military presence at that time[19]. By June 2024, approximately 166,000 active-duty U.S. troops- representing 12.8% of the total force- were still stationed overseas [20].

In 2021, the HIV incidence in active-duty U.S. military was 21 cases per 100,000 service members, slightly higher than that of the general U.S. population, which was approximately 13.9 per 100.000 [21].

Between 1990 and 2024, the Department of Defense conducted over 46 million HIV screening tests, reflecting an extensive and ongoing surveillance effort aimed at early detection and prevention. A total of 1,581 active-duty service members were diagnosed with HIV between January 2017 and June 2022, with 62% remaining on active duty following their diagnosis [22].

These trends are particularly relevant given the global mobility of U.S. forces and their deployment in diverse environments, often under operational stress or during humanitarian missions, which may complicate prevention efforts [23].

In sub-Saharan Africa, HIV/AIDS has disproportionately impacted military personnel compared to civilians. This increased vulnerability is linked to demographic factors- mostly young, sexually active men- and the specific conditions of military service, such as extended time away from home, deployment to unstable regions, and social dynamics that encourage risky sexual behavior [15,16,24].

In 2014, Lloyd et al. reported that the prevalence of HIV among military men from sub-Saharan Africa and other low-income settings was notably higher compared with civilian men of reproductive age, and even higher among longer-serving service members [25]. In 2024, Grillo et. al revealed that military members were frequently involved in dense HIV transmission networks, alongside the civilian population and female sex workers [26].

The Perspective on HIV/AIDS in the Romanian Army

Military personnel infected with HIV but without any functional deficiency (e.g., those who are asymptomatic, experiencing acute retroviral syndrome, or presenting with generalized persistent lymphadenopathy) or who have only low functional impairment (e.g., clinical manifestations due to HIV infection; constitutional symptoms; herpes zoster; idiopathic thrombocytopenic purpura; or peripheral neuropathy) are not classified as having a disability and are allowed to continue performing their military duties [27].

Risk Factors for HIV in the Military

Military populations are considered to be at an elevated risk for acquiring HIV infection [12] due to exposure to a multitude of risk factors. The composition of military forces- mostly young, sexually active males- places them in a higher-risk demographic compared to the general population [25]. Frequent deployments that often result in extended separation from stable partners may further increase the tendency to engage in unsafe sexual practices [28]. The mobility of military troops and exposure of personnel to high-prevalence settings also contribute to this risk [11, 26].

Sexual risk behavior is an essential driver of transmission. In 2015, Hakre et al. reported that among HIV seroconverters in the U.S. Army between 2012 and 2014, most reported multiple sexual partners, inconsistent condom usage, and casual sexual contact or anonymous partners in the year before diagnosis [10].

A culture of masculinity and peer pressure has been reported to contribute to the encouragement of sexual risk-taking behaviors among military personnel [29], influencing HIV-related practices and increasing vulnerability to infection [30].

Tran et al. reported in 2019 that in the Armed Forces of the Republic of the Congo, alcohol consumption, commonly reported among active-duty soldiers, has also been shown to encourage risky sexual habits such as a reduction in condom usage; an increase in transactional sex and multiple sexual partners compared to the lower risk peers [31]. Similar patterns were reported on by Harbertson et al. in 2019, in the U.S. Marine Corps, where a reduction of condom use was associated with alcohol abuse or drug use to enhance sexual experiences [32].

Institutional barriers that may delay diagnosis, prevention, and linkage to healthcare within the military population include concerns over confidentiality and fear of stigma or professional consequences [33], furthering a decrease to essential social and medical care, such as ART [34].

HIV Prevention Strategies and Program Implementation in Military Settings

HIV epidemiology and prognosis have improved substantially due to the universal use of ART, the availability of medications that are more effective and better tolerated by patients [35], and the introduction of preventive measures such as pre-exposure prophylaxis (PrEP) [36]. With a timely diagnosis followed by early initiation of ART, the life expectancy of individuals living with HIV has significantly increased [37, 38].

The Department of Defense (DoD) in the United States of America offers the TRICARE program as part of its efforts to reduce the spread of HIV. This program includes a range of services aimed at both HIV prevention and care. Key initiatives include coverage for pre-exposure prophylaxis (PrEP), as well as promoting access to treatment options such as ART. Additionally, TRICARE provides counseling and support services, and it covers HIV testing for beneficiaries identified as being at risk for contracting the infection [23, 39].

Nonetheless, public health initiatives still encounter obstacles. Misconceptions about HIV transmission are prevalent among people of reproductive age in developing countries and represent a barrier to effective prevention efforts [40,41]. Promoting medical education and raising awareness around HIV-related stigma may have a positive impact on lowering risky sexual behaviors, particularly among military populations [42, 43].

The Department of Defense HIV/AIDS (DHAPP) of the United States of America implements an extensive HIV/AIDS prevention program with various strategies and interventions. These include index case HIV testing, periodic updates to military HIV policies, promotion of condoms, and facilitating access to them. DHAPP also conducts training to prevent stigma and discrimination related to HIV/AIDS [44].

In 2011, Singh and Banerjee conducted a survey among regimental officers regarding hiv prevention in the armed forces and found that there were difficulties in program implementation, especially in the promotion of condom use [45]. In 2015, Tran et al. reported that distributing free condoms to military personnel with improved packaging and a more pleasant scent led to an increase in usage among servicemembers, thereby enhancing efforts to prevent sexually transmitted infections within the military community [46].

Anastario et al. conducted in 2012 a pilot study in a military unit in Barbados, where a modified version of the Popular Opinion Leaders (POL) intervention was used. This intervention involved selecting and training Popular Opinion Leaders within the military personnel to promote conversations on condom use. As a result, there was a noticeable rise in condom use among military personnel after the intervention [47].

CONCLUSION

HIV/AIDS continues to pose a serious health challenge on a global scale, even as progress has been made in recent years. The prevalence of the disease remains a significant social and public health concern, with millions of individuals affected worldwide.

In military settings, targeted prevention strategies are particularly important due to the specific occupational and behavioral risks associated with service. Various armed forces have adopted structured programs aimed at limiting transmission, supporting personnel living with HIV/AIDS, and addressing stigma within military environments.

By focusing on education, encouraging risk-reduction behaviors, and ensuring access to services such as PrEP and ART, military institutions play a key role in HIV control. Sustained implementation of these measures can help transition HIV/AIDS from a widespread public health threat to a manageable chronic condition.

Conflicts of interest and sources of funding

Morphological characteristics of the celiac-mesenteric trunk

P. Bordei[1], R. Baz[1], V. Rusali[1], Cristian R. Jecan[2,3], V. Ardeleanu[1,4,5,6]

Abstract: *The present paper describes the morphological characteristics of 12 celiac-mesenteric trunk cases highlighted by angiography-computed tomography (CT), characteristics met only in male cases (1.82% of the cases). In relation to the vertebral column, the origin of the trunk was found in the the upper half of the L1 vertebra – intervertebral disk between L1 and L2 vertebrae. At the level of its origin from the aorta, the celiac-mesenteric trunk had an external diameter with values ranging from 8.7-13.4 mm, the aortic ostium of the celiac-mesenteric had a vertical diameter ranging from 8.8 to 13.1mm, the horizontal diameter values ranging from 8.8 to 11.2mm. At the level of its origin, the celiac-mesenteric trunk and the aortic wall had an angle with values ranging from 30.0o to 90.2o. The length of the celiac-mesenteric trunk had values ranging from 21.8 to 42.5 mm, most frequently met values were ranging from 30.7 to 33.5mm. At the level of its bifurcation, the celiac-mesenteric trunk had an angle with values ranging from 82.2 to 120,7, most frequently met values were over 90o. The celiac trunk resulted from the celiac-mesenteric bifurcation had an exterior diameter of 6.2 – 10.2 mm, values that in relation to exterior diameter the celiac-mesenteric originated, it represented 65.57 – 92.47% of its external diameter. The celiac trunk up to the end of its ramification had a length with values ranging from 6.3 to 16.8 mm. In all cases being a hepatosplenic trunk, the left gastric aorta originated in the abdominal aorta in 10 cases (83,3% of the cases) and in the other 2 cases, the left gastric aorta originated in one case under the end bifurcation of the celiac trunk whereas the other case in the celiac-mesenteric trunk, before its end bifurcation. The superior mesenteric artery resulting from the ramification of the celiac-mesenteric trunk had an external diameter with values ranging from 4.4 to 8.5 mm that represented 44.44 – 85.06% of the external diameter of the celiac-mesenteric trunk.*

Keywords: *celiac-mesenteric trunk – morphological characteristics*

INTRODUCTION

The celiac trunk and the superior mesenteric aorta are collateral branches of the abdominal aorta that are originating independently from its trunk, assuring the vascularization of the biggest part of the digestive tube and its annexed glands as well as the vascularization of the spleen. There have been cases where both arteries originated from the aorta through a common trunk, the celiac-mesenteric trunk, with frequencies of [1] and 3% [2, 3] – most authors pointing a percentage between 1.0 and 2.5% of the cases. According to [4], during the embryonal development, out of the 4 roots of the omphalomesenteric artery, roots 2 and 3 will disappear and the persistent root will unite by longitudinal anastomosis resulting into left gastric artery. The persistent root will give birth to the celiac trunk and the other one will issue the superior mesenteric artery. In the case where the first and the fourth root disappear, then the celiac-mesenteric trunk will originate.

MATERIAL AND METHODS

The material for this study comprised of 16 angiography-computed tomography (CT), performed with GE LightSpeed VCT high image resolution 64-slice CT system and GE LightSpeed 16- slice CT system, both systems within the

premises of the Clinical Emergency County Hospital "Sf. Andrei" in Constanta. The above-mentioned 12 cases were studied out of 2220 patients that presented for a specialist consult for various medical reasons, during the period between July 2012 and June 2016, in Dobrogea area of the country, south - eastern part of Romania. From the total number of patients, 830 were females (37.39%) and 1390 were males (62.61%). The study was conducted with respect to the following parameters: the level of origin of the celiac-mesenteric trunk from the aorta in relation to the vertebral column, the trajectory and the angle formed from the origin of the celiac-mesenteric trunk with the aortic wall, the exterior diameter as well as the endovascular diameter of the celiac-mesenteric trunk at the level of its aortic origin, its length up to its bifurcation, the angle formed between its two terminal branches as well as the diameter and the trajectory.

RESULTS

In the present study, we met 12 cases with celiac-mesenteric trunk (0.54% of the total cases), all male cases (0.86% of the male cases). In relation to the vertebral column, the origin of the trunk was located in the upper half of the L1 vertebra – intervertebral disk between L1 and L2 vertebrae. In 7 cases (58.33% of the cases) the origin was located at the level of the upper half of the L1 vertebra, most frequently near the upper margin of the vertebral body. In 3 cases (25% of the cases), the celiac-mesenteric trunk originated in the lower half of the L1 vertebra, whereas in 2 cases (16.67% of the cases) it originated at the level of the intervertebral disk L1 – L2.

The celiac- mesenteric trunks originating from the aorta was located higher than the origin of the renal arteries, at a distance of 8.9 – 20 mm from the right renal artery, respectively 9.2 – 22.8 mm from the left renal artery. This indicates that the right renal artery originates most frequently from the aorta than the left renal artery.

The celiac-mesenteric trunk originating from the aorta had an external diameter with values ranging between 8.7 to 13.4 mm, in 8 cases (66.67% of the cases) with a diameter ranging between 11.4 and 13.4 mm. By comparing the external diameter of the celiac-mesenteric trunk with the external diameter of the abdominal aorta at the level of its origin, we have discovered differences in values, ranging from 9.3 to 13.8 mm between the two diameters, representing 40.09 – 58.01% of the external aortic diameter.

The aortic ostium of the celiac-mesenteric trunk had a vertical diameter with values ranging from 8.8 to 13.1 mm – the horizontal diameter ranged between 8.4 to 11.2 mm. In all cases the aortic ostium had an oval shape. In 8 cases (66.67% of the cases) the long axis was horizontal and in 4 cases (33.33% of the cases), the axis was vertical. By comparing the vertical diameter of the aorta, the ostium trunk had a vertical diameter with values ranging between 34.92 to 55.26% of the aortic one, whereas in the case of the horizontal diameter it presented with values ranging between 41.79 to 54.37% of the horizontal aortic diameter.

At the level of its origin, the celiac-mesenteric trunk created and angle with the aortin wall, with values ranging between 30° to 90.2° – extreme values had been found in one for each value, most frequent value for the angle being of 60°. This explains the trajectory of the celiac-mesenteric trunk, most frequently position being transverse anterolateral to the right, an aspect met in 10 cases (83.33% of the cases) and only 2 cases having a horizontal trajectory (transversal) presenting with an angle of 90,2° respectively 90,3°.

The length of the celiac-mesenteric trunk had values ranging between 21.8 to 42.5 mm, most frequently met values ranging from 30.7 to 33.5 mm.

The bifurcation of the celiac-mesenteric trunk into the two arteries had an angle with values ranging from 82.2° to 120.7°, most frequently met values being over 90° (83.33% of the cases). In the case that, after the bifurcation, the superior mesenteric artery had a transverse anterolateral to the right trajectory, the celiac trunk would always be ascending to the right, sometimes close to a vertical position.

The celiac trunk resulting from the celiac-mesenteric bifurcation had an external diameter with values ranging from 6.2 to 10.2 mm, extreme values have been met in only one case for each value; the rest of the cases with values ranging between 8.0 to 9.2 mm. In relation to the external diameter of the celiac-mesenteric trunk from which it originated, the celiac trunk had an external diameter with smaller values by 0.7 to 4.2 mm, representing 65.57 – 92.47% of its external diameter.

The length of the celiac trunk up to its ending ramification had values ranging between 6.3 to 16.8 mm – extreme measures were found in only one for each case. All cases presented with a hepatosplenic trunk with the left gastric artery originating from the abdominal aorta in 10 cases (83.33% of the cases), at a distance of 15.1 – 18 mm above the origin of the celiac-mesenteric trunk. In one case, the left gastric aorta originated from the terminal bifurcation of the celiac trunk whereas in the other case it originated from the celiac-mesenteric trunk before its ending ramification.

The endovascular ostium of the celiac trunk had a vertical diameter with values ranging from 7.1 to 8.6 mm, with a horizontal diameter of 6.6 to 8.6 mm. In 11 cases (91.67% of the cases) the horizontal diameter was bigger than the vertical diameter by 0.5 – 1.3 mm, thus having an oval-shaped horizontal long axis. In only one case (8.33% of the cases) the diameter of the ostium was bigger vertically than horizontally, with a difference of 0.5 mm thus having an oval shape with a vertical long axis.

The superior mesenteric artery resulted by the ramification of the celiac-mesenteric trunk had an external diameter with values ranging between 4.4 to 8.5 mm, smaller by 1.3 – 5.9 mm, representing 44.44 – 85.06% of the external diameter of the celiac-mesenteric trunk.

Table: Percentage frequency of the celiac-mesenteric trunk

Author	CMT frequency	Differences
Adachi	2.4 %	- 1.86 %
Babu	2.79 %	- 2.25 %
Chen	0.7 %	- 0.16 %
Eaton	0.54 %	0
Ferrari	1.7 %	- 1.16 %
Jones	1.7 %	- 1.16 %
Kornafel	1.5 %	- 0.96 %
Lippert	3 %	- 2.46 %
Lipshutz	2.4 %	- 1.86 %
Matusz	0.68 %	- 0.14 %
Michels	2.5 %	- 1.96 %
Mu CG	0.98 %	- 0.44 %
Natsume	0.60 %	- 0.06 %
Nelson	2.0 %	- 1.46 %
Panagouli	0.76 %	- 0.22 %
Piquand	2.0 %	- 1.46 %
Rio Branco	3.0 %	- 2.46 %
Song	1.06 %	- 0.52 %
Yadov	2.5 %	- 1.96 %
Our study	0.54 % of the total cases	0.86 % male cases

The endovascular ostium of the superior mesenteric artery had a vertical diameter with values ranging from 6.8 to 8.5 mm, with a horizontal diameter of 6.2 to 8.5 mm. In 11 cases (91.67% of the cases) the horizontal diameter was bigger than the vertical diameter by 0.3 – 1.1 mm, having an oval shape with a horizontal long axis. In only one case (8.33% of the cases) the diameters of the ostium were equal, thus having a round shape.

By comparing the external diameters of the celiac trunk and the superior mesenteric aorta, we have discovered that in 11 cases, the superior mesenteric aorta had a smaller diameter than the celiac trunk, representing 47.83 – 83.33% of the diameter of the celiac trunk and only in one case the diameter of the celiac trunk was smaller than the one of the superior mesenteric artery, representing 83.73% of its diameter.

DISCUSSIONS

Analyzing the results, we had and comparing them to the data in the existing literature referring to the morphological characteristics of the celiac-mesenteric trunk, we have discovered there is no thorough description of these, most authors mentioning only the frequency as a vascular variation.

By comparing the results of the study with the data existing in the literature we had the possibility to consult, we discovered that our results were the same with the results of [1], whereas in the rest of the cases we found differences with values ranging from 0.06 to 2.46%. Compared with the statistics of [5, 6, 7, 8, 9, 10] our results were smaller with values ranging between 0.06% [5] and 0.52% [10]. Compared with [11] the results we had were smaller by 0.96% and values ranging from 1 to 2.25% we most frequently met [Adachi, cited by 8, 12, 13, 14, 15, 16, 17, 18, 19]. Babu [19] is the only author mentioning the frequency of the celiac-mesenteric trunk in both genders – our results on male cases being smaller by 0.46%. Unlike our study where the presence of the celiac-mesenteric trunk was met only in male cases, Babu [19] discovers the presence of celiac-mesenteric trunk having a wider spread within female cases (1.47% of the cases). In relation to the statistics of [2, 3], the results are lower, the difference being by 2.46%. Lippert [3] discovers the presence of the gastro-hepato-spleno-mesenteric trunk in 2% of the cases, a difference of 1.95% from our study, and the hepato-spleno-mesenteric trunk with the origin of the left gastric aorta from the aorta in 1% of the cases, a difference of 0.55% from our study. Babu [19] finds that in 3 cases (15.79% of the met celiac-mesenteric trunks), the origin of the left gastric aorta was in the celiac trunk resulted from the celiac-mesenteric bifurcation at the level of the abdominal aorta. In a case described by Anupama [20], from the celiac trunk resulted the hepatic artery, the splenic artery, the left gastric artery and a branch that participated in formation of the gastro-duodenal artery. In the specialist literature, we have not met celiac-mesenteric trunk cases where the left gastric artery originated anteriorly to the ending ramification of the celiac-mesenteric trunk, closer to its origin.

The length of the celiac-mesenteric trunk given by Anupama [20] is of 13.00 mm, Tugrul [21] specifics a length of 13.42 mm, both values being smaller than the ones we found in our study by 8.80mm, respectively 8.38 mm smaller than the minimum length and 29.5 mm, respectively 29.08 mm smaller than the length we have measured in our study.

With regards to the diameter of the celiac-mesenteric trunk, Tugrul [21] finds an external diameter of 13.98 mm, a diameter bigger by 0.58 mm than what we have measured for the maximum value and with 5.28mm bugger than the minimum diameter. Compared to our results Tugrul [21] finds the celiac trunk resulting from the celiac-mesenteric bifurcation with a diameter (7.09 mm) bigger by 0.89 mm from the minimum diameter and smaller by 3.11 mm from the maximum value of the diameter we have measured. At the level of the superior mesenteric artery Tugrul [21] finds a diameter of 5.25 mm, bigger by 0.86 mm from the minimum diameter and smaller by 3.25 mm than the values of the maximum diameter we have measured in the study. Hemanth [22] finds an external diameter of 8.7 mm for the superior mesenteric artery, bigger by 4.3 mm than the minimum diameter, respectively by 0.2mm than the maximum value within our study.

CONCLUSION

There is a relatively low frequency of celiac-mesenteric trunk cases described in the literature, our case having the lowest frequency. The differences between different authors is related to the number of cases they have studied and due to the fact that cases where the hepatic artery was the only one originating from the trunk weren't taken into consideration as well as the methods used for the research. There is a difference between the classical methods (dissections, intramuscular injections) in relation to the modern methods, especially MDCD that has better results than the conventional angiography [17, 23]. With modern exploration methods, it has been noted that a greater number of vascular variants and malformations have been observed than those reported in the specialist literature involving other methods. We could add as a cause to the differences and the probable existence of some peculiarities related to the geographical area, which exist between authors who carried out their research on different meridians of the world.

We consider the name of vascular malformation used by some authors when talking about the celiac trunk is not the correct name, whereas vascular variant seems a more appropriate name since all vascular branches of the two arteries are present, having the same morphological characteristics as in the case where they originated independently from the aorta, also because they don't affect the vascular territories they serve.

The present study is interesting not only for a morphologist but also, knowing the different types of anatomical variants is fundamental for the planning of abdominal surgical procedure and is important to the radiologist as well, as specified by [10, 23].

Abstract: Psoriasis is a chronic and complex disease that consists of characteristic cutaneous lesions and is frequently accompanied by systemic comorbidities caused by the chronic inflammatory state. The most common such comorbidities are hypertension, diabetes mellitus, dyslipidemia, inflammatory bowel diseases, depression, anxiety, neoplasia, and non-alcoholic fatty liver disease. Therefore, it is of utmost importance to simultaneously treat both psoriasis and the associated conditions with the best therapies available to improve patients' life quality. Therefore, this review aims to evaluate the effects of biological therapies on both psoriasis and its comorbidities and also to highlight other future options.

Keywords: psoriasis, chronic inflammation, biological therapies

INTRODUCTION

Psoriasis is a chronic, immune-mediated inflammatory disease that affects approximately 125 million people, or around 2% of the world population [1-3]. It has a bimodal incidence, with peaks between 16-20 years and between 57-60 years, with almost 70% of the cases before the age of 40 years [4]. On the other hand, due to an increase in life expectancy, the number of patients with psoriasis who are over 65 years is increasing, and that represents a therapeutic challenge, as the treatment has to be modulated in order to prevent drug interactions and not interfere with other comorbidities [4].

Psoriasis is mainly characterized by specific cutaneous lesions, but also by systemic involvement, the most frequent associated comorbidities being hypertension, diabetes mellitus, dyslipidemia, depression, anxiety, neoplasia, and non-alcoholic fatty liver disease [1,5]. The most common form of psoriasis is psoriasis vulgaris, which consists of well-defined erythematous plaques covered with silvery scales, most often found on knees, elbows, and scalp [6,7]. Other possible forms are guttate psoriasis, which affects most frequently children and young people, usually after streptococcal infections, and consists of small, teardrop lesions on trunk and extremities, pustular psoriasis, a rare form, which is characterized by sterile pustules, and inverse psoriasis, which affects flexion surfaces [7,8]. In severe cases, psoriasis can evolve toward an erythrodermic form affecting over 90% of the body surface, a condition that requires urgent medical intervention [9]. The pathophysiologic mechanisms are represented by an abnormal activation of the immune system, especially of T helper lymphocytes – Th1 and Th17, the next step being the production of proinflammatory cytokines like tumor necrosis factor alpha (TNF-α), interleukin 17 and 23 [10]. The result is the proliferation of keratinocytes and local inflammation, with the formation of the characteristic psoriasis plaques [10].

The diagnosis is mainly clinical, but there are also a few methods that can help in confirming the diagnosis, like reflectance confocal microscopy, which can show an increase in the size and number of dermal papillae, along with a dilation of capillary vessels, and dermoscopy [11,12].

In this review, we aim to evaluate the psoriasis-associated comorbidities and to identify the best therapeutic approach in order to treat the patient as a whole.

PSORIASIS-ASSOCIATED COMORBIDITIES

The main link between psoriasis and all the comorbidities involved is the systemic inflammation, mediated by pro-inflammatory cytokines like tumor necrosis factor alpha (TNF-α), and interleukin (IL) 17 and IL-23 [2]. This inflammation process involves mainly the vessels, aggravating atherosclerosis and making the cardiovascular diseases the most important comorbidities in patients with psoriasis, leading to a decrease in life expectancy of approximately 4-5 years [13-15]. Also, the risk of cardiovascular diseases is increased by over twofold in patients with psoriasis, independently of other risk factors, especially in severe forms and in patients under the age of 50 years, the mechanism involved being vascular inflammation that affects mainly coronary arteries and promotes early atherosclerosis [3,13,16]. Another very important aspect is that dyslipidemia, characterized by high levels of triglycerides and low-density lipoprotein cholesterol (LDL) and low levels of high-density lipoprotein cholesterol (HDL), has an essential role in the relationship between psoriasis and cardiovascular diseases [17]. Therefore, a correct management of the lipid levels is very important in order to lower the cardiovascular risk [17].

Obesity is another important comorbidity with a greater prevalence in patients with psoriasis, the severity of the last one being proportional to the body mass index [18]. The relationship between obesity and psoriasis is bidirectional. Psoriasis, due to chronic inflammation, leads to insulin resistance, promotes visceral fat deposition, and, in severe forms, limits mobilization, all of which increase the risk of becoming overweight. On the other hand, obesity is associated with a great number of pro-inflammatory adipokines, like leptin, and a low number of anti-inflammatory ones, an imbalance that aggravates local and systemic inflammation and also increases the risk of psoriasis by over one and a half times [18-21]. Another fact worth mentioning is that obesity can reduce the treatment efficiency due to a larger distribution volume and, therefore, indirectly aggravate the severity of psoriasis [19]. Moreover, almost 50% of the patients with psoriasis have metabolic syndrome, defined as the presence of at least three of the following: abdominal obesity (waist at least 102 cm in men and at least 88 cm in women), insulin resistance or increased level of blood glucose (at least 100 mg/dL), dyslipidemia (tryglicerides at least 150 mg/dL and/or HDL under 40 mg/dL in men and under 50 mg/dL in women), arterial hypertension (over 130/85 mmHg) [22]. The presence of metabolic syndrome is very important, as it is linked with a greater prevalence of cardiovascular diseases, fact that creates a vicious circle [20]. In addition, osteoporosis is more frequently encountered in patients with psoriasis due to the activation of the osteoclasts by the pro-inflammatory cytokines, and it also aggravates the prognosis [23].

Diabetes mellitus is one of the most frequent diseases worldwide and also a common comorbidity associated with psoriasis, both by chance and by similar pathophysiological mechanisms, the first link between these two diseases being noted as early as 1897 [14,24]. As it was already mentioned, psoriasis is characterized by systemic inflammation that can lead to insulin resistance and promote visceral fat deposition, mechanisms that can increase the risk for developing diabetes by up to two times compared with the general population [22]. Moreover, diabetes may be induced in certain patients with psoriasis by the use of corticosteroids in an attempt to control the severity of the disease, especially if other therapies are lacking [23].

Regarding mental ailments, patients with psoriasis have a greater risk than the general population, especially for depression, anxiety, and suicide [2]. The explanation is that the presence of cutaneous lesions leads to shame, low self-esteem, and isolation from other people, all of which result in a reduction of the quality of life [2]. In addition, a low level of melatonin is very frequent in this category of patients and may contribute to depression by inducing changes in the sleep pattern [25].

Table 1: Common hepatic adverse reactions of classical psoriasis treatment

Treatment	Effects on the liver	Sources
Methotrexate	• significant toxicity • can induce hepatic fibrosis and cirrhosis if used long time, especially in NAFLD	[32,33]
Cyclosporine A	• can increase lipid levels and favor hepatic steatosis • treatment should be carefully monitored in NAFLD	[34]
Acitretin	• can aggravate dyslipidemia and NAFLD in patients with metabolic syndrome	[35]
Dimethyl fumarate	• has a better safety profile and can reduce hepatic inflammation and oxidative stress • however, the liver function should be monitored carefully	[36]

NAFLD – non-alcoholic fatty liver disease

Last, but not least, one of the most common comorbidities recently associated with psoriasis is non-alcoholic fatty liver disease (NAFLD) [26]. It consists of excessive deposition of lipids in the liver that is not caused by alcohol consumption and that can progress to non-alcoholic steatohepatitis (NASH) and cirrhosis [27]. Epidemiological studies indicate that the prevalence of NAFLD is three times higher in this category of patients and also that the severity of psoriasis is proportional to that of NAFLD [28-30]. Moreover, an interesting study has revealed that almost 47% of the patients with psoriasis had NAFLD, and 22% even had biopsy-confirmed NASH

[29]. The diagnosis of NAFLD is established through imagistic methods like abdominal echography and elastography and laboratory tests for liver function, and fully confirmed by liver biopsy [31]. It is worth mentioning that NAFLD has a significant impact not only on the liver but also on other systems, including the heart, kidneys, and thyroid gland, which have to be carefully evaluated [29]. Thus, the combination of psoriasis and NAFLD leads to a greater cardiovascular risk and mortality, emphasizing once again the importance of treating the patient as a whole [28]. However, some of the therapies available for psoriasis can have a direct impact on the liver and be dangerous, especially if patients already have NAFLD [31]. Table I highlights the most common adverse hepatic reactions.

The dermatologist has an essential role in the early identification of psoriasis-associated comorbidities. The general management consists of carefully evaluation of the liver function and of cardiovascular risk using physical examination – body mass index calculation, arterial pressure, signs of dyslipidemia like the presence of xanthomas, imagistic methods – abdominal echography, liver elastography, coronarography in selected cases and laboratory tests, a wise choice of medication, especially in the presence of NAFLD, where biological therapies are the first recommended, and inclusion of non-pharmacological treatment options like a healthy diet with anti-inflammatory products and physical activity [13,17,18,27].

However, an integrated approach is mandatory for a correct and complete treatment, the most commonly involved medical fields being cardiology, gastroenterology, and psychology [37].

TREATMENT OF PSORIASIS AND ITS ASSOCIATED COMORBIDITIES

The treatment of psoriasis has significantly evolved in the last century, from empirical therapies to modern biological medications based on a more profound understanding of the pathophysiological mechanisms [19]. Initially, between 1920 and 1950, the treatment of psoriasis was focused on the clinical aspect, and the most common medications included arsenic, coal tar, salicylic acid, and dithranol [19]. In the 1950s, significant progress had been made by the development of topical corticosteroids, a very efficient form of medication, that rapidly became the gold standard of the treatment due to anti-inflammatory properties, but which lacked specific targets [38]. Moreover, if used extensively, adverse reactions occurred in the form of skin atrophy or tachyphylaxis [39]. A more important step toward better control of psoriasis was made when methotrexate and cyclosporine were discovered, both of them used in severe forms of psoriasis, but are also limited by the risk of significant hepatic and kidney adverse reactions or toxicity [32].

Table 2: Treatment of psoriasis: benefits on comorbidities, risks, and side effects

Medication	Benefits on comorbidities	Risks	Side effects	Sources
Methothrexate	↓systemic inflammation ↓cardiovascular risk	can aggravate NAFLD	hepatotoxicity	[32,33]
Cyclosporine	rapid control of severe psoriasis ↓ inflammation	arterial hypertension dyslipidemia	nephrotoxicity	[34]
TNF-α inhibitors (Infliximab, Adalimumab, Etanercept, Certolizumab)	↓ inflammation ↓cardiovascular risk ↓ risk of hepatic fibrosis ↓ insulin resistance first line in psoriatic arthritis	↓ efficiency in overweight patients modest weight gain	infections, especially TB autoimmune diseases: SLE or arthritis hepatotoxicity congestive HF rare: lymphoma and skin cancer	[49]
IL-17 inhibitors (Secukinumab, Ixekizumab, Brodalumab)	↓ inflammation improve dyslipidemia of choice in overweight patients	may ↑ IBD	fungal infections, especially local/systemic candidosis and respiratory infections pain, erythema, edema at the site of the injection rare: autoimmune diseases – SLE-like, anterior uveitis	[44,50]
IL-23 inhibitors (Guselkumab, Risankizumab, Tildrakizumab)	↓ inflammation ↓ insulin resistance improve hepatic function very good in the long term, with no negative impact on comorbidities	none	respiratory tract infections, especially viral pain, erythema, and edema at the site of the injection rare – autoimmune diseases – less frequent than with TNF-α or IL-17 inhibitors	[50]
Dual IL-12/23 inhibitors (Ustekinumab)	↓ vascular inflammation improve endothelial dysfunction	none		[51,52]
Small molecules (Apremilast)	↓ systemic inflammation improve glycemic metabolism modest weight loss, which can be of benefit	diarrhea		[53,54]

HF – heart failure; IBD – inflammatory bowel disease; IL – interleukin; NAFLD – non-alcoholic fatty liver disease; SLE – systemic lupus erythematosus; TB – tuberculosis; TNF-α – tumor necrosis factor alpha; ↓ - lower; ↑ - increase/aggravate

The true revolution of psoriasis treatment, especially of the severe forms, was provided by biological medication, which targeted specific inflammatory cytokines and modulated the pathophysiological mechanisms involved [40]. However, significant side effects are also common, therefore, a good collaboration with other subspecialities is mandatory [40]. The main representatives of this therapeutic class are: TNF-α inhibitors, IL-17 inhibitors, IL-23 inhibitors, and dual IL-12/23 inhibitors [41,42]. Of particular importance regarding comorbidities are the effects of these therapies on atherosclerosis, as a main cardiovascular risk factor. It is evaluated using the thickness of the intima and media of the vessels as measured by echography, the pulse-wave velocity, the aspect of the atherosclerotic plaques by CT angiography, and the level of C-reactive protein [43]. For example, it was revealed that IL-17 inhibitors like secukinumab significantly reduce the thickness of the intima and media of the vessels and also the arterial rigidity, much more than classical treatments like methotrexate and cyclosporine [44]. On the other hand, they seem to not affect the vascular inflammation evaluated by PET/CT or on metabolic markers like insulin or adiponectin [43]. Further studies are necessary to better explore these effects, especially in the long term, in order to simultaneously reduce both the severity of psoriasis and of cardiovascular risk, eventually by using therapies that target multiple cytokines at the same time [45].

As was mentioned before, another very frequent psoriasis-associated comorbidity is obesity, with almost 50% of the patients with psoriasis having metabolic syndrome [18,21,22]. Hence, a wise choice of medication is mandatory, especially because not all the therapeutic classes are effective in this context [13,37,46,47]. For example, TNF-α inhibitors have low efficiency in overweight patients and can even lead to an increase in weight [37,46,47]. IL-17 inhibitors, IL-23 inhibitors, and also small molecules (Apremilast) are of choice in this situation, due to their improvement in dyslipidemia, insulin resistance, and weight loss [47].

Last, but not least, NAFLD is a very important comorbidity that has to be taken into consideration when choosing a therapeutic approach, especially in patients with severe psoriasis, in whom this comorbidity also has a high prevalence [28,29]. Methotrexate or cyclosporine should be avoided if NAFLD is suspected, because they can aggravate it [28,47]. In this context, a much better solution nowadays is represented by the use of biological therapies, especially of TNF-α inhibitors, which can decrease the risk of hepatic fibrosis and decrease inflammation and dyslipidemia [1,48].

For an easier understanding, the most common therapies used in psoriasis are presented in Table 2, along with their benefits on psoriasis-associated comorbidities, risks involved, and the most important side effects.

NON-PHARMACOLOGICAL MANAGEMENT OF PSORIASIS AND ITS ASSOCIATED COMORBIDITIES

As was mentioned before, in this category of patients, it is of utmost importance to adopt an integrative approach, from modification of the lifestyle to a careful selection of the best medications in order to have as many benefits as possible with the minimum of side effects. Interventions on the lifestyle are mainly represented by aerobic exercises for at least 150 minutes per week, which reduce the risk of obesity and also improve the lean mass and the glucidic metabolism, management of the stress and of anxiety, and by adopting a healthy diet [46,55]. This last aspect is very important, as the Mediterranean diet is well documented to reduce inflammation and to prevent metabolic comorbidities [46]. It consists of healthy fats like olive oil, good quality proteins from fish, chicken, or eggs, fibers, vitamins, and minerals from fresh fruits and vegetables, and also of cereals and fermented dairy products [56]. In psoriasis, the Mediterranean diet has many important benefits: it reduces systemic inflammation, insulin resistance, and dyslipidemia and, consequently, reduces the risk of atherosclerosis, obesity, and NAFLD [46,55]. Regarding alcohol consumption, in modest quantities, the red wine has antioxidative properties due to resveratrol, but the frequent use has to be discouraged because it has a negative impact both on the severity of the disease, increasing the levels of pro-inflammatory cytokines like TNF-α and IL-17 that can aggravate the skin lesions and NAFLD, and on the treatment adherence and efficiency [46,57].

Table 3: Plants most commonly used in psoriasis

Plant	Effects	Sources
Aloe vera (Aloe barbadensis miller)	↓ local inflammation ↑ skin hydration prevents exfoliation	[58,64]
Turmeric (Curcuma longa)	– TNF-α – IL-6 ↓ local inflammation	[58,59]
Fish oil (Omega-3)	↓ systemic inflammation ↑ skin hydration ↑ PASI score	[56,58]
Chamomile (Matricaria chamomilla)	soothing skin effects ↓ local inflammation ↓ pruritus	[58,60]
Capsicum (Capsicum annuum)	↓ pain and pruritus ↓ local inflammation sometimes can irritate the skin	[58,65]
Fenugreek (Trigonella foenum-graecum)	↓ local inflammation ↑ skin barrier	[58,66]

IL – interleukin; TNF-α – tumor necrosis factor alpha; ↓ - decrease; ↑ - increase; – - inhibits

Medicinal plants are used in psoriasis as associated therapies due to their anti-inflammatory, antioxidative, and immune modulation properties. Even though the efficiency of these therapies is not well studied, some plants significantly reduced the symptoms of the disease when taken orally or applied topically [58]. Some of these plants are Aloe vera (Aloe barbadensis miller), Curcuma longa, omega-3 rich fish oil, Matricaria chamomilla, Capsicum annuum, and Trigonella foenum-graecum [58]. Aloe vera hydrates the skin and reduces local inflammation, while curcumin inhibits pro-inflammatory cytokines like TNF-α și IL-6 [58,59]. Omega-3 fatty acids from fish oil modulate the immune response and can decrease the severity of cutaneous lesions [56,58]. In addition, chamomile has soothing effects and is frequently topically utilized [60]. Last, but not least, capsaicine, which is a chili pepper extract, has analgesic and anti-inflammatory properties, decreasing pruritus and redness when used topically, while fenugreek can also be used orally, with similar anti-inflammatory and anti-oxidative characteristics [61–63]. On the other hand, future studies are needed to better explore their properties, and, because of this, patients must visit a specialist before taking any of these plants to prevent side effects or drug interactions. These plants and their properties in treating psoriasis are presented in Table 3.

CONCLUSION

Psoriasis is a complex disease, with a multitude of comorbidities that significantly affect the quality of patients` lives. Thus, the concomitant treatment is essential in reducing the risks, and a careful selection of the medication is mandatory, as not to aggravate the pre-existing or newly appeared conditions. The most common psoriasis-associated conditions are cardiovascular diseases, especially due to systemic inflammation that promotes early atherosclerosis, obesity, metabolic syndrome, dyslipidemia, NAFLD, diabetes, mental ailments like anxiety and depression, neoplasia, and inflammatory bowel disease. The greatest mortality is caused by cardiovascular diseases, the prevalence of them being over two times higher in patients with psoriasis. Consequently, pro-active management is essential, using both pharmacological and non-pharmacological measures, ideally in a personalized manner.

The novel, modern therapeutic options, which include biologic therapies, are very promising. They reduce systemic inflammation by targeting specific cytokines involved in the pathogenesis of psoriasis, like TNF-α, IL-17, IL-23, and, therefore, can improve both the cosmetic appearance and other conditions, especially when concurrently used with non-pharmacological interventions. Of them, IL-17 inhibitors seem to be of real benefit in reducing atherosclerosis and ameliorating cardiovascular diseases, the most dangerous risk in psoriasis patients. Also, IL-23 inhibitors and the small molecules (Apremilast) are of choice in overweight patients, decreasing dyslipidemia, insulin resistance, and obesity. Moreover, TNF-α inhibitors reduce the risk of NAFLD.

It can be concluded that nowadays there are many therapeutic options for treating psoriasis, and novel therapies targeting specific pathophysiological mechanisms that can modulate both psoriasis and its associated conditions. However, further studies are necessary to better identify the long-term effects of these modern, biological therapies.

Abstract: Periodontal disease is a chronic pathology, resulting from the action of microbial communities that become dysbiotic, accompanied by immune response impairment in periodontal tissues, leading to an inflammatory process that promotes progressive tissue destruction. Abnormal activation of nucleotide-binding oligomerization domain (NOD-), leucine-rich repeat (LRR-), and pyrin domain (PYD)-containing protein 3 (NLRP3) promotes chronic inflammation. Research shows that leptin and oxidative stress (OS) are involved in the activation of the inflammatory pathways, including the activation of the NLRP3 inflammasome. In this context, the main objective of our study was to determine the levels of the NLRP3, leptin, and total antioxidant capacity (TAC) in the saliva of patients with periodontal disease. The present cross-sectional study included 44 patients with periodontitis, while the control group was represented by 19 clinically and biologically healthy adults. Saliva samples were collected from all participants in the study, and salivary levels of NLRP3, leptin, and TAC were determined using the Enzyme-linked immunosorbent assay (ELISA) and commercial kits. The results show that NLRP3 had statistically significantly increased levels in the study group versus the control group ($p< 0.00001$). Although TAC was also increased in the patients compared to the healthy subjects ($p=0.491$), no statistically significant differences were found. On the other hand, leptin levels were significantly lower in periodontitis patients compared to the control group ($p< 0.00001$). The results obtained in the present study are promising, but further studies are needed to obtain a more comprehensive understanding of the complex molecular mechanisms underlying periodontal disease.

Keywords: periodontal disease; NLRP3 inflammasome; leptin; TAC; saliva

INTRODUCTION

Around 700 species of oral bacteria form the oral microbiome [1], a term used by molecular biologist and Nobel Prize laureate Joshua Lederberg [2, 3] to define the mixture of symbiotic, commensal, and pathogenic microorganisms present in our organism [4]. Periodontal disease is a chronic inflammatory disease [5] with origins in the dental plaque [6], being a result of microbial communities that become dysbiotic, corroborated with immune response impairment in periodontal tissues, leading to an inflammatory process that promotes progressive tissue destruction [7, 8].

Accepted: 27 September 2025

In the beginning, the inflammation induced by anaerobic bacteria [6] leads to gingival bleeding, pain, and swelling, which are clinical traits of gingivitis, which affects almost 90% of the population and is considered to be the mildest form of periodontal disease [9, 10]. The progression of the disease, in the lack of appropriate treatment, leads to irreversible attachment loss of the periodontium and alveolar bone destruction, thus causing periodontitis [9], which, if left untreated, results in tooth loss [11, 12].

Periodontal disease affects not only the quality of life of the patients because of the associated symptoms and dysfunctions, but also has a considerable effect on society, even from an economic point of view [13], becoming a global health burden [14]. Moreover, by favoring the transfer of periodontal pathogens and pro-inflammatory agents to other tissues, periodontal disease has been linked to systemic diseases [15], including diabetes and heart disease [9], respiratory infections [16], Alzheimer's disease [17], neurodegenerative diseases[18], autoimmune diseases, and even malignancy [19].

Recent research has shown that the development of periodontal disease is not promoted only by bacterial, but also by viruses, environmental factors (e.g., smoking) and lifestyle of the host, and it involves genetic mechanisms and immune response [5, 7], new studies focusing on the development of alternative therapies such as vaccines or antioxidant agents to improve the prevention of the disease [20].

The activation of inflammasomes represents one of the core pathways linked to inflammatory diseases [21]. The nucleotide-binding oligomerization domain (NOD-), leucine-rich repeat (LRR-) and pyrin domain (PYD)-containing protein 3 (NLRP3) inflammasome [22], found in the cytosol, is a supramolecular complex that comprises receptor protein NLRP3, adapter protein ASC (apoptosis-associated speck-like protein containing a caspase recruitment domain) and caspase-1 [23]. These three components of the inflammasome have different functions. While receptor protein NLRP3 can detect endogenous danger signals and enlist downstream targets [23, 24], ASC links NLRP3 to caspase-1, which is involved in cytokine release and pyroptosis (inflammatory cell death) [22, 24, 25] via gasdermin D [24]. NLRP3 can be activated by cellular alterations [23], microbial infections, or environmental stimuli [26]. The activation of NLRP3 leads to protease caspase-1 activation, which in turn promotes the production of cytokines IL-1β and IL-18, thus upholding inflammation [26]. Furthermore, abnormal activation of NLRP3 promotes chronic inflammation, hence being involved in the development of numerous diseases [25], such as cardiovascular diseases [27], metabolic diseases [25], autoimmune diseases [28], cancer [25], periodontal disease [29], and, as it was recently discovered, COVID-19 [30].

So, the NLRP3 inflammasome is responsible for the transformation of IL-1β, one of the most important pro-inflammatory cytokines linked to periodontal disease, into its biologically active form [31]. This mediator of inflammation can induce osteoclast differentiation, thus playing a crucial role in alveolar bone resorption, specific to periodontitis. Moreover, NLRP3 activation mediates osteoblasts' apoptosis via IL-1β and IL-18, affects the fibroblasts in the periodontal ligament via IL-1β and IL-6, and is involved in leukocytes' regulation in inflamed periodontal tissue [32].

Research shows that leptin and reactive oxygen species (ROS) can activate inflammatory pathways, including the NLRP3 inflammasome [33]. Leptin, a peptide hormone produced primarily by adipocytes [34], is involved in the regulation of food intake, additionally having an important role in proinflammatory immune responses [35]. It is also produced by the salivary glands, which are responsible for leptin storage and secretion as well [36]. In periodontal disease, leptin has been shown to be able to regulate the ratio between osteoprotegerin and receptor activator of nuclear factor kappa beta (RANKL) in gingival fibroblasts [37], hence influencing bone remodeling [38]. In a recent study conducted on mice, Han et al revealed that leptin promotes macrophage polarization in periodontitis via NLRP3 inflammasome [39]. Furthermore, leptin was found to promote oxidative stress (OS) [40].

OS has already been proven to be one of the key players in periodontal disease development and progression, contributing to tissue destruction and tooth loss [41]. OS is characterized by the loss of balance between oxidants and antioxidants, promoting the formation of ROS and free radicals, which can play an important role in inflammation, despite their reduced lifespan [42]. In periodontal disease, the activation of the innate immune system produces a storm of proinflammatory cytokines and overproduction of ROS [41]. On the other hand, in chronic inflammation, such as the one present in periodontitis, overproduction of ROS, mainly by neutrophils [43], can not only induce OS, and activate proteolytic enzymes but can also activate different signaling pathways [44].

In order to investigate the complex mechanisms involved in the pathogenesis of this condition, the main objective of our study was to determine the levels of the NLRP3, leptin, and TAC (total antioxidant capacity) in the saliva of periodontitis patients.

MATERIALS AND METHODS

Study groups

The present cross-sectional study included 44 patients with periodontitis, diagnosed according to the 2018 AAP/EFP Classification of Periodontal & Peri-implant Diseases [45, 46].

Inclusion criteria for the study group:

- Presence of at least 14 teeth on both dental arches combined;

- Interdental clinical attachment loss (CAL) is detectable in ≥2 non-adjacent teeth or buccal/ oral CAL ≥3 mm with periodontal pocket depth >3 mm is detectable in ≥2 teeth;

- CAL cannot be attributed to non-periodontal causes such as:

1) gingival recession of traumatic origin;

2) dental caries extending into the cervical area of the tooth;

3) presence of CAL on the distal aspect of a second molar and associated with malposition or extraction of a third molar;

4) a combined endo-periodontal lesion;

5) occurrence of a vertical root fracture [46].

Exclusion criteria for the study group:

- chronic alcohol consumption;
- administration of contraceptive medication;
- pregnancy or breastfeeding;
- periodontal treatment less than 6 months before sampling.

Among the 46 patients initially recruited from the Periodontology Department of the Faculty of Dentistry, "Carol Davila" University of Medicine and Pharmacy, and two private practices, 2 were excluded because they had active autoimmune diseases, which could have altered the results, given the fact that inflammation is also at the center of these pathologies.

The control group was represented by 19 clinically and biologically healthy adults with no periodontal disease, other oral disorders, and any known systemic pathology.

All the participants in this study were informed about the aim of the study and their voluntary participation. It was also explained to them that by agreeing to take part in the research, they would have no additional risks to their periodontal treatment, nor any costs or benefits of any kind. Moreover, the subjects included in the study were assured of their anonymity in the processing and publication of the data obtained. Furthermore, they were informed of the right to freely withdraw from this study at any time without any type of repercussions or penalties. After they completely understood the nature and purpose of this research, they signed the informed consent. This study was approved by the Ethics Committee of the Carol Davila University of Medicine and Pharmacy (22976/17.08.2022).

Sample collection and biomarker determination

All subjects included in our study received written information regarding the collection procedure before sampling. Saliva was collected during their next appointment, in the morning, between 8 and 10. They were recommended to avoid food and drink intake, as well as any oral hygiene method, for 12 hours before the collection of the sample. If this was not possible, they had to refrain from eating and drinking for at least 60 minutes before sampling.

Additionally, smoking and chewing gum were also restricted in the last hour before the sample collection, while physical effort was forbidden 30 minutes before the collection. Another requirement was to avoid using lipstick or similar products that morning. In order to remove food scraps and exfoliated cells, each participant in the study rinsed their mouth with distilled water before the collection of the samples.

During the procedure, they were advised to relax, not swallow, and not communicate with others. Three mL of unstimulated total saliva was collected from each participant in the study. Once retrieved in sterile tubes, the saliva was transported to the laboratory on ice in a special transport box for biological samples. Samples were then centrifuged at 3000 rpm for 15 minutes and aliquoted. Until further analysis, they were kept in the freezer, at -80°C.

The three biomarkers investigated in this study were determined using the Enzyme-linked immunosorbent assay (ELISA) and commercial kits (DRG Instruments GmbH, Germany – TAC and leptin; Abbexa LTD, Cambridge, UK for NLRP3). The determination of all parameters was performed according to the instructions of the manufacturer.

Statistical analysis

All the data from the study were analyzed using IBM SPSS Statistics 26 (IBM, USA). Data were expressed as means ± std. Deviation, as well as medians, depend on the distribution's normality. The Shapiro-Wilk test was used to evaluate data distribution. The non-parametric Mann-Whitney U test was then applied to compare quantitative independent variables between the groups. Correlations were assessed using Spearman's rho correlation coefficient. A p-value lower than 0.05 was considered statistically significant.

RESULTS

The patient group included 44 subjects, among whom 21 were males (47%). The mean age was 51.8 ± 9.9 years, with a median of 51.5 years. The average number of remaining teeth in the patient group was 21.8 ± 4.6, with a median of 23. Eleven patients (25%) suffered from hypertension, diabetes mellitus, hyperthyroidism, or osteoporosis. The control group was represented by 19 healthy subjects, among whom 5 were males (26%). Their mean age was 28.5 ± 13.8 years, with a median of 19 years.

The results obtained show that when all patients with periodontal disease were compared with the control group, NLRP3 had statistically significantly increased levels in the study group (Table 1, Figure 1). Although TAC was also increased in the patients compared to the healthy subjects, no statistically significant differences were found (Figure 2). At the same time, leptin was significantly decreased in patients with periodontal disease compared to the control group (Figure 3).

Table 1: NLRP3, TAC and leptin salivary levels in periodontal patients and the control group

Biomarker	Group	Median	Mean ± Std. Deviation	p-value*
NLRP3	Patient	1.1372 ng/mL	1.117 ± 0.332 ng/mL	**< 0.00001**
	Control	0.7382 ng/mL	0.776 ± 0.208 ng/mL	
TAC	Patient	76.741 µmol/L	114.127 ± 119.398 µmol/L	0.491
	Control	70.838 µmol/L	94.553 ± 101.928 µmol/L	
Leptin	Patient	5.894 ng/mL	6.124 ± 2.064 ng/mL	**< 0.00001**
	Control	8.827 ng/mL	8.618 ± 1.478 ng/mL	

**Mann-Whitney U Test*

Figure 1: Salivary levels of NLRP3 in the patient group *versus* the control group

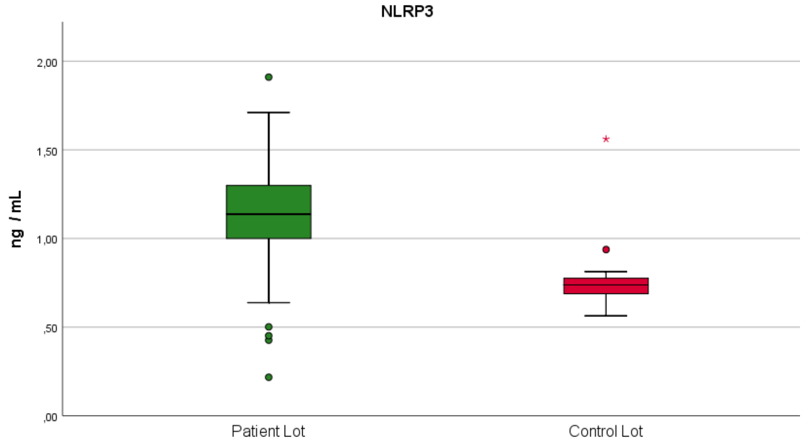

Figure 2: Salivary levels of TAC in the patient group *versus* the control group

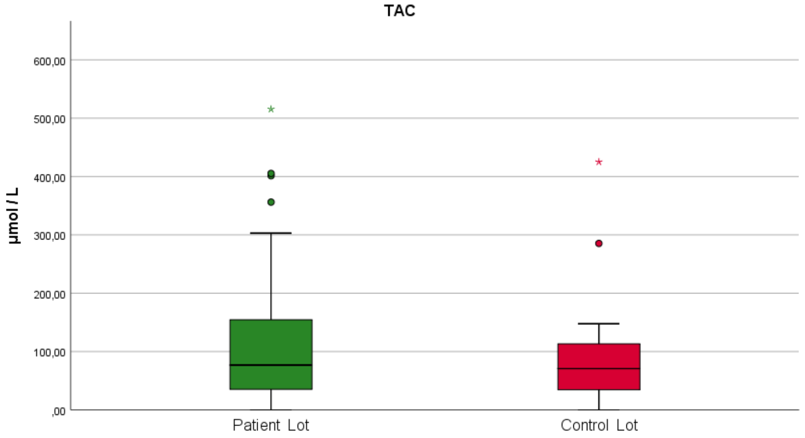

Figure 3: Salivary levels of leptin in the patient group *versus* the control group

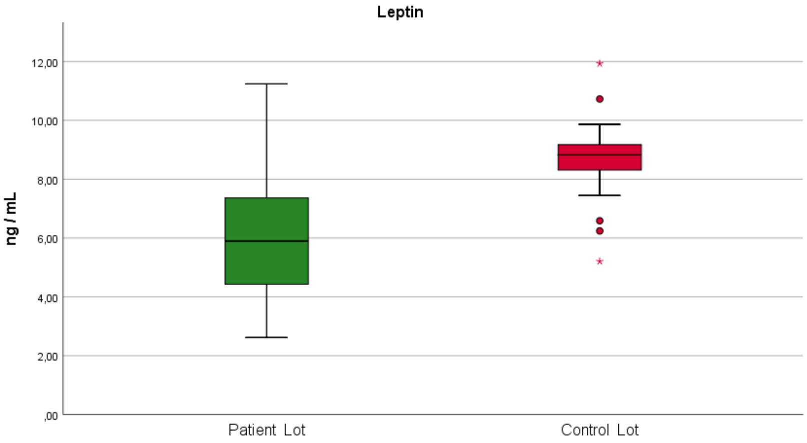

None of the three determined parameters displayed significant differences when comparing patients with periodontitis with no associated systemic disease *versus* patients with periodontitis and associated systemic conditions (Table 2, Figures 4, 5, 6).

Spearman's rank correlation coefficient was used to test intragroup possible associations between salivary parameters. No significant correlation was found between salivary levels of leptin and NLRP3 when including all patients or when analyzing just patients with periodontal disease without associated systemic conditions. Also, no significant correlation was found between salivary levels of NLRP3 and TAC or TAC and leptin when including all patients or when analyzing just patients with periodontal disease without associated systemic diseases. No statistically significant correlations were found between the concentrations of the analyzed biomarkers and the number of remaining teeth when taking into consideration all periodontal disease patients, nor when including only the patients without associated systemic diseases (Table 3).

Table 2: Comparison of the biomarkers' salivary levels in periodontitis with no associated systemic disease *versus* patients with periodontitis and associated systemic conditions

Biomarker	Group	Mean ± Std. Deviation	p-value*
NLRP3	No Associated Diseases	1.13 ± 0.369 ng/mL	0.356
	Associated Diseases	1.077 ± 0.189 ng/mL	
TAC	No Associated Diseases	112.041 ± 112.434 µmol/L	0.828
	Associated Diseases	120.387 ± 115.215 µmol/L	
Leptin	No Associated Diseases	6.346 ± 2.011 ng/mL	0.115
	Associated Diseases	5.457 ± 2.174 ng/mL	

**Mann-Whitney U Test*

Figure 4: Salivary levels of NLRP3 in patients with periodontitis with no associated systemic disease *versus* patients with periodontitis and associated systemic conditions

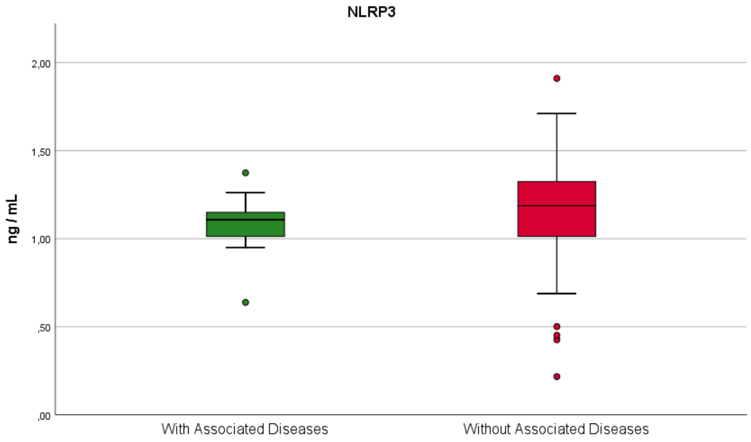

Figure 5: Salivary levels of TAC in patients with periodontitis with no associated systemic disease *versus* patients with periodontitis and associated systemic conditions

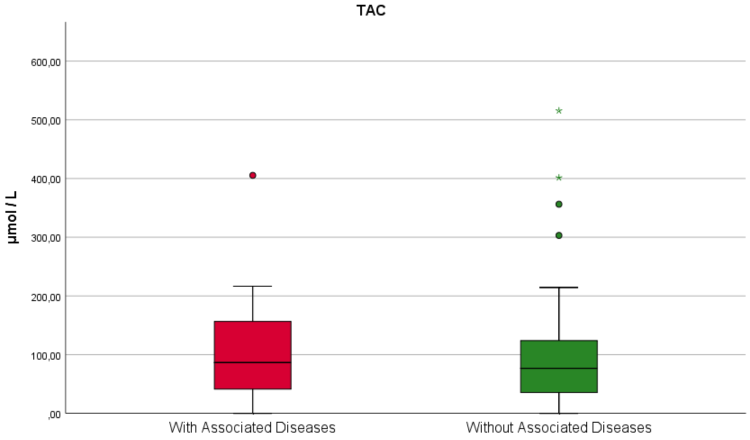

Figure 6: Salivary levels of leptin in patients with periodontitis with no associated systemic disease *versus* patients with periodontitis and associated systemic conditions

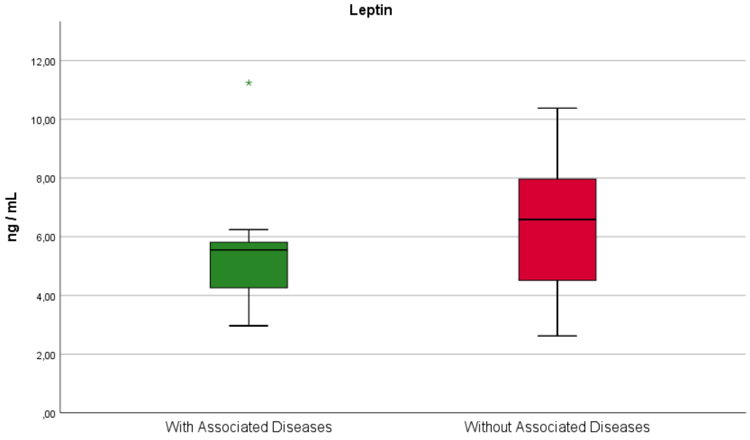

Table 3: Correlations between the determined biomarkers

Correlation	Spearman Rho	p – value
Between the number of remaining teeth and the NLRP3 levels for all patients	0.175	0.255
Between the number of remaining teeth and Leptin levels for all patients	0.095	0.541
Between the number of remaining teeth and the TAC levels for all patients	-0.158	0.305
Between the number of remaining teeth and the NLRP3 levels for patients without associated disease	0.223	0.213
Between the number of remaining teeth and leptin levels without associated disease	-0.063	0.729
Between the number of remaining teeth and leptin levels for patients with associated diseases	0.378	0.252
Between the number of remaining teeth and the TAC levels for patients without associated disease	-0.088	0.626
Between leptin and NLRP3 in all patients	0.147	0.340
Between leptin and NLRP3 in patients with no associated diseases	0.234	0.189
Between TAC and NLRP3 in all patients	-0.171	0.267
Between TAC and NLRP3 in patients with no associated diseases	-0.131	0.467
Between TAC and leptin in all patients	-0.168	0.276
Between TAC and leptin in patients with no associated diseases	-0.059	0.746

DISCUSSION

Saliva has already proven to be a reliable diagnostic, prognostic, and monitoring fluid for both oral and systemic diseases, being very rich in molecules and macromolecules that can be used as biomarkers [48]. Furthermore, the collection procedure is easy, it is more efficient in terms of costs, has a lower risk of cross-infection compared to the blood, and most importantly, the sampling is non-invasive [48, 49]. However, when determining the salivary levels of these biomarkers, we have to keep in mind that their concentrations are frequently decreased compared to the blood. Additionally, there are several factors that can influence their levels, including the moment of the day or the level of stress [49].

In recent years, inflammasomes have represented a major research interest due to their potential to determine an inflammatory response by integrating signals from different pathogens and altered cells [50, 51]. The most studied of the inflammasomes in systemic diseases, NLRP3, has also gained attention regarding its connection with periodontal disease [52]. The dysbiosis and inflammation associated with periodontal disease lead to the activation of the components of the NLRP3 inflammasome. Apart from promoting pyroptosis and neutrophil recruitment, once activated, NLRP3 promotes the overproduction of cytokines and antibodies, as well as the release of prostaglandin E2. In the end, all these events result in the destruction of the periodontium [53].

The results of previous studies performed on animal models were not conclusive. Yamaguchi et al induced periodontal disease in mice by orally injecting them with Porphyromonas gingivalis, showing that this microbial species, involved in the inflammatory process characteristic of chronic periodontitis, activated the NLRP3 inflammasome, leading to a response from the cells of the innate immune system and involvement of the IL-1 family of cytokines [54]. Nevertheless, a recent study by Rocha et al. performed on mice with induced periodontal disease revealed different results, showing that the inflammation associated with periodontitis and the consequent bone resorption was not determined by NLRP3, which played a minor role in the process, but rather by caspase-1 [55]. The results of our study showed statistically significant increased salivary levels of NLRP3 in patients with periodontitis compared to the control group ($p < 0.00001$, Table 1, Figure 1), suggesting a possible association of NLRP3 with the pathogenesis of this oral condition. Furthermore, the data we obtained did not show any correlation between NLRP3 salivary levels and the number of remaining teeth on the dental arches (Table 3).

When comparing the salivary levels of NLRP3 in patients with periodontitis and without systemic diseases to those who have associated systemic diseases, we were unable to find any statistically significant difference (Table 2). These results indicate that NLRP3 levels are mainly due to the presence of periodontal inflammation and not to the coexistence of other pathologies. Isola et al reported that patients with periodontitis and patients with periodontitis and type 2 diabetes had increased NLRP3 levels, both in the serum and saliva, not only compared to healthy controls, but also versus patients who had type 2 diabetes, but did not have periodontal disease [53]. Using samples from the gingival crevicular fluid and gingival biopsies, Garcia-Hernandez et al. showed that patients with periodontitis and uncontrolled type 2 diabetes displayed upregulated genes and proteins associated with NLRP3 activation compared to patients who had only periodontitis [56].

A systematic analysis from 2020 concluded that the levels of leptin both in plasma and saliva reported in the analyzed studies were too different, and although a decrease in salivary levels of leptin was observed in periodontal patients compared to healthy subjects, that data was not sufficient to establish the relationship between the disease and levels of leptin [57].

Similar to other studies, our results showed that leptin had significantly decreased levels in the saliva of patients with periodontal disease compared to those of the control group ($p < 0.00001$, Table 1, Figure 2) [58]. Leptin has already been shown to activate NLRP3 inflammasome in other inflammatory diseases, including systemic lupus erythematosus, and autoimmune disease characterized by the presence of the inflammatory process [59]. Despite both NLRP3 and leptin showing increased levels in periodontitis, we could not find a correlation between the two biomarkers.

TAC was defined by Miller as the "measure of the antioxidant capacity of all antioxidants in a biological sample and not just the antioxidant capacity of a single compound” [60]. Since ROS are naturally counteracted by antioxidants, determining the total antioxidant capacity has become one of the common and important ways to monitor the effect of oxidative stress in periodontal disease. However, the results regarding TAC levels in periodontal disease are controversial, with research showing both significant increases in periodontitis patients compared to healthy controls, as well as no significant differences [61].

On the other hand, Toczewska et al reported lower levels of TAC in both the saliva (which was a mixture of non-stimulated and stimulated saliva) and the gingival crevicular fluid of periodontal patients [62]. A decrease in the antioxidant capacity of patients with periodontal disease was also reported by Diab-Ladki et al [63]. Moreover, similar results were obtained by Brock et al, although their data did not show a statistically significant difference for salivary levels [64]. In our study, the determination of TAC displayed higher salivary levels in periodontitis patients compared to the control group ($p=0.491$, Table 1, Figure 3), but no statistical significance was found. This difference could be explained by the fact that the control group consisted of healthy subjects who had a mean age lower than that of the periodontitis patients. Limberaki et al previously reported that, contrary to expectations, younger people have lower TAC levels in the serum than older people [65].

Previous research revealed that while mitochondrial dysfunction and ROS overproduction can promote NLRP3 activation, their existence is not imperative for this to happen. Additionally, DNA damage caused by ROS can activate the inflammasome, but its release can happen downstream of the activation of the inflammasome [66]. This could explain why our results showed no statistically significant correlation between the salivary levels of NLRP3 and those of TAC.

Our study has several limitations, including the study groups being relatively small. Additionally, there was a significant mean age difference between the study group and the control group. Moreover, although saliva was collected following the same recommendations for all participants in the study, the salivary flow of each participant could have played a role in the level of the biomarkers [67]. Nevertheless, they reveal that the data obtained by our research group suggests the involvement of NLRP, leptin, and oxidative stress in periodontitis.

CONCLUSION

The results obtained in the present study are promising, but they incite further research that should be more focused on the relationship between these biomarkers and other factors that could influence the outcome, for example, the different types of bacteria involved in periodontal disease. Moreover, analyzing not just the saliva of the patients, but their gingival crevicular fluid could provide better insights. Future perspectives could be offered by determining these biomarkers in dynamic, before and after periodontal treatment, as well as correlating them to clinical parameters. All these represent objectives for our future research, which would offer a more complete picture of the mechanisms involved in periodontal disease development and progression and thus, show how NLRP3 activation can promote periodontal tissue destruction and bone loss.

Conflicts of interest and sources of funding

The authors declare no conflict of interest. This research was funded by Carol Davila University of Medicine and Pharmacy, Bucharest, Romania, through Contract no. 33PFE/30.12.2021 funded by the Ministry of Research and Innovation within PNCDI III, Program 1—Development of the National RD system, Subprogram 1.2—Institutional Performance—RDI excellence funding projects.

Abstract: Since February 24, 2022, military personnel of the Ukrainian Defense Forces have been resisting the military aggression of the Russian Federation. The fighting and the mobilization of men for military service complicated the well-being of Ukrainian families. The purpose of the article is to identify the relationship between the choice of coping strategies and post-traumatic stress disorder (PTSD) and maladaptation indicators in married and unmarried mobilized military personnel. Ukrainian Defense Forces military personnel (n=171 males, between 20 and 60 years of age) took part in this study. The "Strategic Approach to Coping Scale", "Mississippi Scale for Combat-Related Posttraumatic Stress Disorder", and "Disadaptation Express Questionnaire" were used. Correlation and exploratory factor analysis made it possible to identify the structure of coping strategies in mobilized servicemen with different family statuses and to determine the relationships between coping strategies, PTSD, and maladaptation indicators. The pre-war experience of using coping strategies by married and unmarried mobilized military personnel was not a sufficient barrier to the emergence of PTSD symptoms and maladaptation manifestations. Married and unmarried mobilized servicemen had a deficit structure of coping strategies characteristic of war.

Keywords: military personnel; coping strategies; PTSD; family; combat stress; mental health; mobilized soldiers; Russian-Ukrainian war

INTRODUCTION

The large-scale war in Ukraine, which began on 24.02.2022, has exacerbated the problem of mobilizing civilians and preparing military personnel to participate in hostilities to protect the sovereignty and lives of Ukrainians [1]. However, mobilization for military service has also complicated the well-being of families, who are forced to overcome problems arising from threats to the health and lives of family members, changes in family lifestyle, and everyday difficulties on their own, without men/women. This was also due to military actions on the territory of the country: experiencing threats of air raids, loss of housing, forced displacement, distance learning for children and their permanent stay at home, remote work or its absence, etc. [2,3]. These circumstances were factors that destroyed families, as well as additional stress for military personnel who, while defending their country, cannot protect and preserve their families.

Coping with potentially traumatic situations, including combat stress, involves the use of coping mechanisms and stress management strategies [4]. One of the models of stress management is the "Multiaxial Model of Coping", which comprises three axes: active–passive, prosocial–antisocial, and direct–indirect [5]. These axes represent dimensions of general coping strategies that allow for broader application across individualistic and collectivist cultures. The model assumes that active and avoidant strategies are not socially indifferent, and ignoring this fact may lead to a misinterpretation of their effects [6]. Prosocial coping involves strategies that positively utilize social resources. Antisocial coping includes behaviors that, while

satisfying the individual’s needs, can be detrimental to others [7]. Aggressive coping is also effective as long as it does not become outright antisocial. Antisocial coping does not denote psychopathological behaviors, but rather coping methods that can be potentially harmful to others, involving the use of others or even exploiting them for personal gain [8].

Research has detailed the negative impact of combat deployments on service members and their families, the devastating effects of maladaptation and post-traumatic stress disorder (PTSD) symptoms on families, including violence against spouses and children [9,10]. PTSD couples reported clinically significant levels of relationship distress several times more frequently than comparison couples, both for general distress and across all specific problem areas (e.g., aggressive behavior, quality of leisure time together, sexual functioning, conflicts about finances and child rearing) [11]. Another study found that greater unit support, marital satisfaction, and psychological hardiness were associated with less anger, anxiety, depression, and PTSD symptomatology in soldiers [12]. The positive effects of intimate partner [13] and unit support reduced negative emotionality and traumatic stress only for veterans with less severe combat experiences [14].

However, the conducted studies did not examine the features of PTSD manifestations and maladaptation to the choice of coping strategies of mobilized servicemen with different family statuses. For such people, military service was not their own choice, and they were forced to adapt their civilian traumatic experience to overcome the effects of combat stressors and wartime stress factors.

The purpose of the article was to identify the relationship between the choice of coping strategies and indicators of post-traumatic stress disorder and maladaptation in married and unmarried mobilized military personnel.

MATERIALS AND METHODS

Study design and participants

This study was an exploratory descriptive study. All participants provided their informed consent for inclusion before engaging in the study. Ukrainian Defense Forces military personnel (n=171 males, aged 20 to 60 years, with a mean age of 41.84±6.49 years) participated in this study. The participants included 71% privates and 29% non-commissioned officers, all of whom participated in the Russian-Ukrainian war and had combat experience ranging from 6 to 10 months (8.75±2.58 months). Before the war, 62% of the participants had urban origins, while 38% had rural origins; 24% had completed secondary education, 57% had completed secondary specialized education, and 19% had attained higher education. The military personnel were sent to the rehabilitation center from combat positions to partake in a psychological recovery program lasting 14 days [15]. Two groups were formed to conduct the study: group 1 included 76 unmarried participants, while group 2 consisted of 95 married mobilized military personnel. The participants were identified based on various manifestations of acute stress reactions, significant negative experiences—including signs of depression and suicidal ideation—presence of PTSD symptoms, sleep problems (more than 50%), somatic complaints (more than 80%), and wounds and contusions (more than 75%); they also faced difficulties in returning to combat missions due to the consequences of illness, injury, and wounds. Female military personnel were excluded from this study because less than 0.5% of female combatants participated throughout the program period. Officers were also not included in the study due to their small number in the psychological recovery program (less than 1%). Participants were randomly selected for the study.

Ethical approval

The study was conducted in accordance with the Declaration of Helsinki and was approved by the Institutional Ethics Committee of the National Academy of the National Guard of Ukraine, Kharkiv, Ukraine (protocol code 2024/12, dated September 24, 2024).

Instruments

To determine the relationship between the choice of coping strategies and indicators of PTSD and maladaptation in mobilized military personnel, the “Strategic Approach to Coping Scale” (SACS), “Mississippi Scale for Combat-Related Posttraumatic Stress Disorder” (MSCRPTSD), and “Disadaptation Express Questionnaire” (DEQ) were used.

The SACS was used to determine coping strategies and behavior patterns of military personnel to overcome stressful situations, adapted into Ukrainian [16,17]. The SACS consists of 54 statements, the answers to which were given on a 5-point Likert scale (Cronbach’s $\alpha = 0.846$). The scale allowed for the choice of coping strategies (behavior models) such as “Assertive Actions” (Cronbach’s $\alpha = 0.627$), “Social Joining” (Cronbach’s $\alpha = 0.736$), “Seeking Social Support” (Cronbach’s $\alpha = 0.746$), “Cautious Actions” (Cronbach’s $\alpha = 0.676$), “Instinctive Actions” (Cronbach’s $\alpha = 0.691$), “Avoidance” (Cronbach’s $\alpha = 0.669$), “Indirect Actions” (Cronbach’s $\alpha = 0.654$), “Antisocial Actions” (Cronbach’s $\alpha = 0.687$), and “Aggressive Actions” (Cronbach’s $\alpha = 0.724$). The results were analyzed by comparing the data on the degree of expression (low, medium, high) of a specific person’s coping behavior for each subscale with the average values of the coping stress models.

The MSCRPTSD [18] was used to diagnose PTSD in military personnel on missions in the war zone, adapted into Ukrainian [17, 19]. The scale consists of 35 statements (4 subsets), the answers to which were given on a 5-point Likert scale (Cronbach’s $\alpha = 0.88$). Subset 1 (11 statements) describes the symptoms of the “intrusion” group when the traumatic event is constantly repeated in the experience in one (or more) ways. Subset 2 (11 statements) relates to the symptoms of the “avoidance” group when there is a constant avoidance of stimuli associated with trauma, blocking of emotional reactions, and numbness, which was not observed before the trauma. Subset 3 (8 statements) describes the symptoms of “excitability” when persistent symptoms of arousal increase that were not observed before the injury. Subset 4 (5 statements) describes symptoms associated with guilt and suicidal tendencies. Despite the grouping of statements into 4 subsets, one general indicator was calculated taking into account the conversion of the answer into a score for direct and inverse statements, reflecting the severity of PTSD symptoms (range from 35 to 175 points, where 35-80 points is a variant of the norm; 81-114 points - separate symptoms of PTSD; 115-175 points - clinical manifestations of PTSD, a psychiatric examination and inpatient examination were recommended).

The DEQ was used to identify signs of a violation of the adaptability of the soldier’s personality: violation of the regulatory function of the emotional-volitional sphere and self-esteem; lack of prospects for continuing life and the ability to overcome life’s difficulties (probability of committing suicidal attempts); loss of moral convictions, the likelihood of committing addictive and delinquent acts; loss of communicative potential (comradely support, reduced ability to accept the help of one’s team) [19]. The DEQ consists of 45 statements included in 5 subscales (Cronbach’s $\alpha = 0.848$): “Sincerity of answers” (Cronbach’s $\alpha = 0.719$), “Violation of behavioral regulation” (Cronbach’s $\alpha = 0.736$), “Probability of committing suicide attempts” (Cronbach’s $\alpha = 0.743$), “Violation of moral normativity” (Cronbach’s $\alpha = 0.702$), and “Loss of communicative potential” (Cronbach’s $\alpha = 0.709$). Each positive response was worth 1 point, and each negative 0 points. The overall DEQ scale was calculated as the sum of scores on 4 scales (values on the “Sincerity of answers” scale were not included). The results of the overall DEQ scale were evaluated as follows: 1-10 points - high adaptation to combat operations, sufficient tolerance to adverse mental and physical stress, including under conditions of severe combat stress; 11-14 points - average adaptation, unstable level of performance, especially in combat conditions; 15 points or more - low adaptation (distress and adjustment disorders) that does not meet the requirements for soldiers in combat conditions.

Information on the implementation of a formal translation or back-translation protocol for SACS, MSCR-PTSD, and DEQ is unavailable. The authors of the article did not pilot test or validate the design of the psychodiagnostic instrument used in this study; we used data from the aforementioned Ukrainian sources. We are not aware of any published or internal references that describe the psychometric properties of the Ukrainian versions of these instruments in detail.

Statistical Analysis

The study was conducted in two stages. At the first stage, the use of correlation analysis allowed us to determine the relationships between the indicators of coping strategies, PTSD, and maladaptation in unmarried (group 1) and married (group 2) participants. At the second stage of the study, the indicators of coping strategies, PTSD, and maladaptation were compared in two participant groups. For the data presented, basic descriptive statistics were used (arithmetical mean M, standard deviation SD). The reliability of differences in the results of the mean values in two interrelated groups was determined using Student’s t-test. For the assessment of the statistical significance of differences, we used the level of significance from $p = 0.05$ to $p = 0.001$. No correction for multiple comparisons was applied.

Exploratory factor analysis was used to determine the structure of coping strategies in each participant’s group. Exploratory factor analysis of matrices was carried out using the extraction method (principal component analysis) and the rotation method (Varimax with Kaiser normalization). We did not perform the Kaiser-Meyer-Olkin (KMO) statistic and Bartlett’s test of sphericity for each group. Correlation analysis allowed us to determine the relationships between the identified factors in married and unmarried participants. The study results were statistically analyzed using SPSS 22.0 (IBM, Armonk, NY, USA).

RESULTS

Tables 1–2 present the results of the correlation relationship between the indicators SACS, MSCRPTSD, and DEQ scales by the group 1 and group 2 participants.

Table 3 presents the results of the coping strategies by the group 1 and group 2 participants.

Tables 4–5 present the exploratory factor analysis results of the coping strategies structure by the group 1 and group 2 participants.

Tables 6–7 present the correlation results between the factor structure of coping strategies and indicators of PTSD and maladaptation by the group 1 and group 2 participants.

DISCUSSION

At the first stage of the study, the use of correlation analysis allowed us to determine the relationships between coping strategies and indicators of PTSD, maladaptation in mobilized military personnel with different family statuses. Thus, productive coping “Assertive actions” (p = 0.01), “Social joining” (p = 0.01), and “Seeking social support” (p = 0.01) were associated with lower indicators of PTSD and maladaptation only in married participants (group 2). Such unproductive coping as “Instinctive actions” (p = 0.05), “Avoidance” (p = 0.05), “Indirect actions” (p = 0.05), “Antisocial actions” (p = 0.05) had relationships with the indicators of PTSD and maladaptation only in unmarried participants (group 1). The coping “Aggressive actions” (p = 0.01) was interrelated with the PTSD and maladaptation indicators in both groups of participants. The obtained results allow us to assume that such civilian experience as life in marriage influenced some features of the choice of coping strategies that determine the ability of mobilized servicemen to withstand combat stress factors. Similar studies showed that problem-solving coping reduced PTSD symptoms, while coping strategies aimed at avoiding stressful situations increased them [20]. Our results showed that this relationship is also be influenced by the family status of a serviceman.

As previously noted, social relationships such as intimate partners and military unit support reduced PTSD symptoms and negative emotionality and had a positive impact on military personnel’s well-being [14]. In our study, we assumed the possibility of other variants of these relationships: the maladaptation indicators could have been by receiving specific social assistance (“Seeking social support”), and the symptoms of PTSD were could reduced while maintaining or restoring the ability to engage in general activity (“Social joining”). We found that in group 2, the indicators of choosing such coping strategies as “Social joining” and “Seeking social support” were the highest among all coping strategies, and they differed from the indicators of group 1 (p = 0.05 for both values).

In the second stage of the study, exploratory factor analysis and correlation analysis were used to identify the tentative structure of coping strategies among mobilized military personnel with different family statuses, as well as to determine the relationship between coping strategies and indicators of PTSD and maladaptation.

In group 1, the identified tentative three-factor structure of coping strategies described 70.72% of the variance of features. The factor 1 content was determined by the coping strategies “Seeking social support,” “Social joining,” and “Cautious actions.” This factor was associated with the involvement of additional external resources. Perhaps, when asking for assistance, the group 1 participants were afraid of making a mistake, which could become an additional source of stress. This factor was designated as “Limited search for socially significant assistance.” The factor 2 content was determined by the coping strategies “Antisocial actions”, “Indirect actions”, and “Aggressive actions”. These coping strategies were associated with the abuse of actions to create one’s superiority over others, to create conditions for using the resources of colleagues for one’s purposes. This factor was designated as “Destructive methods of gaining an advantage over others”. The positive pole of factor 3 was determined by the coping strategies “Assertive actions”, and the negative pole “Avoidance”. These coping strategies were associated with one’s confidence and readiness to take responsibility. However, unlike assertive actions in group 2, where they may have been part of the interaction to overcome the consequences of stress factors. In group 1 assertive actions were possibly a component of self-affirmation. This factor was designated “Self-affirmation as a demonstration of decent behavior”.

It should be noted that the group 1 participants showed a tendency where destructive ways of gaining an advantage over others rather increased mental trauma than contributed to protection from the effects of stress factors. In this group, the factor “Self-affirmation as a demonstration of decent behavior” to a certain extent contributed to the reduction of “Disruption of behavioral regulation” (p = 0.05) and “Likelihood of committing suicide attempts” (p = 0.05). Indeed, the self-confidence and assertiveness that characterized the participants in this group may have been characteristics that allowed them to control themselves in a stressful situation.

In group 2, the identified tentative three-factor structure of coping strategies described 69.43% of the variance in features. The content of factor 1 included the coping strategy “Seeking social support,” “Social joining,” and “Assertive actions.” These strategies emphasized the importance of seeking external resources while considering the interests of fellow soldiers to mitigate the effects of combat stress factors. We referred to this factor as “Socially significant methods of attracting external resources.” The content of factor 2 was determined by the coping strategy “Indirect actions” and “Antisocial actions”. This factor was designated as “Socially inconsistent methods of attracting external resources” and had a statistically significant negative relationship with the consequences of the stress experienced: PTSD indicators (p = 0.01) and all maladaptation indicators (p = 0.01). Factor 3 was associated with the coping strategy “Instinctive actions” and “Avoidance”. This factor was designated as “Uncertainty in one’s resources and careful attitude towards them”. The main goal of the described factor structure of coping strategies in group 2 was associated with to attract additional resources and avoid unfavorable circumstances.

In studies that examined the factor structure of coping strategies, three main factors have often been identified: problem-focused coping, getting social support, and avoidance [21,22]. However, we found that all mobilized servicemen had a deficit structure of coping strategies. Moreover, married servicemen had a desire to obtain additional external resources by any means to overcome the effects of combat stress factors, as well as a careful attitude towards their resources. It can be assumed that married servicemen were more oriented towards interaction to overcome stressful situations, while unmarried servicemen were forced to rely more on their strength.

It is a common assertion that the effectiveness of stress attenuation is limited because it is often not possible to avoid stressors, and avoiding or minimizing stress can lead individuals to miss opportunities for performance and growth. Thus, during stressful situations, a more efficacious approach is to optimize stress responses (i.e., promote adaptive, approach-motivated responses) [23]. Another study concluded that an avoidant-focused coping style acts as a vulnerability factor for PTSD symptoms, whereas hardiness acts as a resilience factor against symptom development [24]. Thus, when interpreting coping strategies such as “Cautious actions” and “Instinctive actions”, it is necessary to take into account their role in the overall structure of coping and how personal resources for coping relate to the strength of stressful impacts. Our results partially confirm the conclusions that: (1) a robust latent variable named personal resources (indicated by social support, unit cohesion, and trait resilience) was negatively associated with PTSD severity; (2) personal resources were negatively associated with negative posttraumatic cognitions; (3) negative posttraumatic cognitions fully mediated the association between personal resources and PTSD severity [25].

Study limitations

This study certainly had limitations. 1) The study served as a generalization of experiences from the rehabilitation center focused on the psychological recovery of military personnel following participation in hostilities. This significantly influenced the amount of available empirical data (including sample size and psychodiagnostic survey methods), the study's structure, and the mathematical processing methods used. 2) The research was exploratory, aimed at generalizing the outcomes of surveys of military personnel involved in the psychological recovery program, as well as identifying potential hidden resources and methods for preventing PTSD and maladjustment. 3) Information on the implementation of a formal translation or back-translation protocol for SACS, MSCR-PTSD, and DEQ is unavailable. The authors of the article did not pilot test or validate the design of the psychodiagnostic instrument used in this study; we used data from the Ukrainian sources. We are not aware of any published or internal references that describe the psychometric properties of the Ukrainian versions of these instruments in detail. 4) The risk of false positive results was increased by the fact that no correction for multiple comparisons was applied. 5) Data on resources for building resilience against combat stress factors was limited among mobilized military personnel who did not choose military careers and received very brief training. 6) Existing data on family support for servicemen relates to scenarios where families are safe, a situation not observed in Ukraine, creating an ambivalent role for the family that can serve as both a source of anxiety and a resource. 7) The research was conducted on a sample of servicemen who participated in the psychological recovery program, specifically those exhibiting signs of mental and physical exhaustion, PTSD symptoms, and maladjustment. Consequently, the results related to the characteristics of coping structure deficits in both established variants—typical for married and single mobilized servicemen—should be specifically attributed to the corresponding samples. As a result, it is inappropriate to extend the findings of this study to servicemen who cope more effectively with the impact of combat stress. 8) The results obtained possess low practical value (Cohen’s d); however, they allow us to formulate valuable hypotheses for further research. For example, PTSD prevention may be linked not only to direct family support but also to shared life experiences such as joint problem solving, which remain relevant even in the absence of direct family support, highlighting its value. Additionally, an intriguing hypothesis is the assessment of individual coping: its position within the overall coping strategy framework (which may exhibit signs of collective or individual culture) and the general nature of this structure concerning the situation (for instance, a deficiency in the overall structure indicating a reliance on external assistance). 9) Female military personnel were excluded from this study because less than 0.5% of female combatants participated throughout the duration of the psychological recovery program. 10) The participant sample consisted solely of enlisted military personnel and sergeants; officers did not take part in this study. 11) This study faced limitations due to the brief duration of the psychological recovery program and the need to avoid overloading participants with additional activities that did not align with the program’s objectives, which limited the application of research methods and the repeatability of the survey, among other factors. Finally, the current study was constrained by the absence of an active comparison condition and a longitudinal follow-up. Thus, by summarizing some of the outcomes from the rehabilitation center's work on the psychological recovery of military personnel following military operations, we aimed to attract the scientific community's attention to addressing new urgent challenges in military medicine and psychology, particularly in the unique area of psychological support for mobilized military personnel.

CONCLUSION

The pre-war experience of using coping strategies by married and unmarried mobilized military personnel was a rather weak preventive measure for counteracting combat stressors, and not a sufficient barrier to the emergence of PTSD symptoms and maladaptation manifestations Assertive actions could be associated as a preventive factor for the negative consequences of combat stress only in married military personnel. Perhaps this was due to their structure of coping strategies, in which assertive actions were an integral part of interaction, while in unmarried servicemen it was self-affirmation. The creation of a wide range of social relationships had a positive impact on the preventive power of social interaction, which helped to overcome the consequences of PTSD and social maladaptation manifestations for both groups of mobilized military personnel. Aggressive actions, which became a source of additional stress and a method of responding to stress, were linked to higher PTSD scores.

Psychological support of the family among married mobilized servicemen was associated with the formation of resilience to the action of combat stress factors. In addition, compatible actions of married servicemen in stressful situations due to feedback formed an adequate stress response, reduced the likelihood of meta-experiences. Unmarried mobilized servicemen did not have family experience, so their coping strategies mainly came down to reacting and individual resilience to combat stress factors.

Married and unmarried mobilized servicemen had a deficit structure of coping strategies characteristic of war. They realized that their resilience to the effects of combat stress factors depended on the possibility of receiving help from others. And if married mobilized servicemen were more inclined to exercise caution when spending their resources, then unmarried servicemen tried to use self-assertive behavior as a method to raise their authority and thus attract additional external resources.

Abstract: Background: Labia minora hypertrophy can lead to aesthetic dissatisfaction and functional discomfort among women, affecting their quality of life and sexual self-esteem. Traditional surgical labiaplasty techniques are effective but are associated with higher complication rates and longer recovery times. This study aims to evaluate the efficacy, safety, and patient satisfaction of laser labiaplasty as a minimally invasive alternative for labia minora reduction. Methods: A retrospective analysis was conducted on 60 female patients who underwent laser labiaplasty. Preoperative assessments included medical history, gynecological examination, and patient-reported concerns. The procedure utilized a CO_2 laser for tissue excision without the need for sutures. Postoperative outcomes were evaluated through follow-up visits and telephone interviews, focusing on complications, recovery time, and patient satisfaction measured by the Subjective Global Aesthetic Improvement Scale (sGAIS). Results: The primary motivations for surgery were aesthetic concerns (85%) and functional discomfort (55%). The mean age was 34.7 years. Minor complications included transient postoperative bleeding (10%) and mild discomfort (25%), with no major complications reported. High satisfaction rates were observed, with 92% of patients reporting significant improvement (sGAIS scores of 4 or 5). Conclusions: Laser labiaplasty is an effective, minimally invasive procedure with high patient satisfaction and low complication rates. It offers a viable alternative to traditional surgical methods for women seeking labia minora reduction due to aesthetic or functional concerns.

Keywords: laser labiaplasty; labia minora hypertrophy; patient satisfaction; minimally invasive procedure; genital aesthetics

INTRODUCTION

Labia minora hypertrophy, characterized by the enlargement or elongation of the inner vaginal lips, has been a largely recognized condition [1,2]. Women experiencing this condition often report both aesthetic dissatisfaction and functional issues, such as discomfort during physical activities or sexual intercourse [3,4]. The increased visibility and awareness of genital aesthetics in contemporary society have led to a growing number of women seeking corrective procedures to address these concerns [5,6].

Genital aesthetics significantly impact a woman's sexual self-esteem and overall quality of life [7,8]. Studies have demonstrated that dissatisfaction with genital appearance can lead to psychological distress, reduced sexual function, and decreased confidence [9,10]. The rise of media portrayal of idealized genital images has further influenced women's perceptions, prompting many to pursue medical interventions to achieve their desired appearance [11].

Traditional surgical labiaplasty techniques, including edge resection, wedge resection, Z-plasty, and deepithelialization, have been employed to reduce labial tissue [12,13]. While effective, these methods are associated with risks such as scarring, altered sensation, asymmetry, and extended recovery periods. These potential complications have led both patients and clinicians to explore less invasive alternatives that offer effective results with fewer risks [14].

Laser labiaplasty has emerged as a minimally invasive option that utilizes laser technology to excise excess labial tissue precisely [15,16]. Introduced more than 15 years ago using a neodymium-doped yttrium aluminum garnet (Nd) laser, the technique has evolved with the adoption of carbon dioxide (CO_2) and erbium-doped yttrium aluminum garnet (Er) lasers [17]. These lasers offer advantages such as reduced intraoperative bleeding, minimal thermal damage, and enhanced healing, contributing to improved patient outcomes.

Despite the growing popularity of laser labiaplasty, there is a paucity of comprehensive studies evaluating its efficacy, safety, and patient satisfaction. Most existing literature comprises small case series or focuses on surgical techniques without detailed analysis of patient-reported outcomes [18,19]. This gap underscores the need for robust clinical data to inform practitioners and patients about the benefits and limitations of this procedure. Therefore, the objective of this study is to retrospectively analyze our center's experience with laser labiaplasty in treating labia minora hypertrophy. By examining preoperative motivations, procedural details, postoperative outcomes, and patient satisfaction, we aim to provide valuable insights into the efficacy and safety of laser labiaplasty as a minimally invasive alternative to conventional surgical methods.

MATERIALS AND METHODS

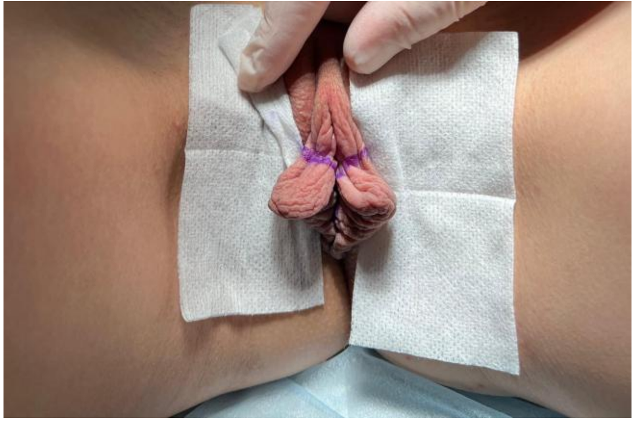
This retrospective study analyzed data from 60 female patients who underwent laser labiaplasty between June 2020 and September 2024. Inclusion criteria encompassed women aged 18 years or older diagnosed with labia minora hypertrophy, who expressed aesthetic or functional concerns and completed a minimum of six months of follow-up. Exclusion criteria included active genital infections, uncontrolled systemic diseases, previous labiaplasty, or other genital surgeries.

All patients underwent a comprehensive preoperative evaluation. Medical and gynecological histories were obtained, focusing on reproductive history, menstrual cycle details, prior pregnancies, and any gynecological conditions or surgeries. Physical examination included measurement of labia minora dimensions using standardized calipers. Preoperative investigations included a Papanicolaou (PAP) smear, vaginal secretion analysis for infections, and a transvaginal ultrasound to assess pelvic anatomy.

The classification of labial hypertrophy identifies three types of labial hypertrophy, based on Stephane Smarrito's study [20]: Type I, known as the "flag," affects the anterior one-third and was found in 11% of the cases; Type II, or the "oblique," involves the middle third and accounted for 29% of cases; and Type III, termed "complete," includes the posterior third, observed in 60% of the patients. Symptomatically, Type I patients typically reported aesthetic concerns and discomfort from tight clothing without dyspareunia. Type II was noted for a fuller appearance, and Type III frequently presented with dyspareunia more so than the other types. Surgical approaches were tailored accordingly, with Type I cases treated using a superior pedicle flap technique for moderate labial resection, while Types II and III were approached with the lambda laser technique. This classification system allows for more targeted surgical strategies that align closely with patient symptoms and expectations, providing a significant improvement over the traditional method based solely on dimensional measurement.

The procedure was performed under local anesthesia. Initially, a topical anesthetic cream containing lidocaine 2.5% and prilocaine 2.5% was applied to the labia minora for 30 minutes. After the removal of the cream and disinfection with povidone-iodine solution, infiltration anesthesia was administered using 1% lidocaine with epinephrine 1:100,000 via a 30G needle. Preoperative markings were made to delineate the extent of tissue excision (Figure 1).

Figure 1: Preoperative markings



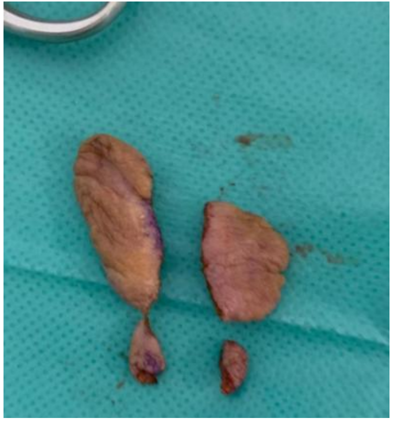
A CO_2 laser (CO_2RE, Syneron Candela) equipped with a surgical handpiece was set to a continuous wave mode at 10 Watts. The laser was used to excise excess labial tissue along the marked lines, ensuring symmetrical reduction and preservation of the natural contour (Figure 2). Hemostasis was achieved through the laser's coagulative properties, eliminating the need for sutures. After the procedure, the area was treated with topical fusidic acid ointment and covered with a sterile dressing.

Patients received detailed postoperative instructions, including applying fusidic acid ointment twice daily for one week; maintaining local hygiene with gentle cleansing using mild soap and water; avoiding sexual activity, strenuous exercise, swimming pools, and saunas for six weeks; and wearing loose-fitting clothing to minimize friction.

Follow-up visits were scheduled at one week, one month, three months, and six months postoperatively. Evaluations focused on wound healing, identification of any complications, and assessment of patient satisfaction using the Subjective Global Aesthetic Improvement Scale (sGAIS), a validated 5-point scale ranging from 1 (no improvement) to 5 (very significant improvement).

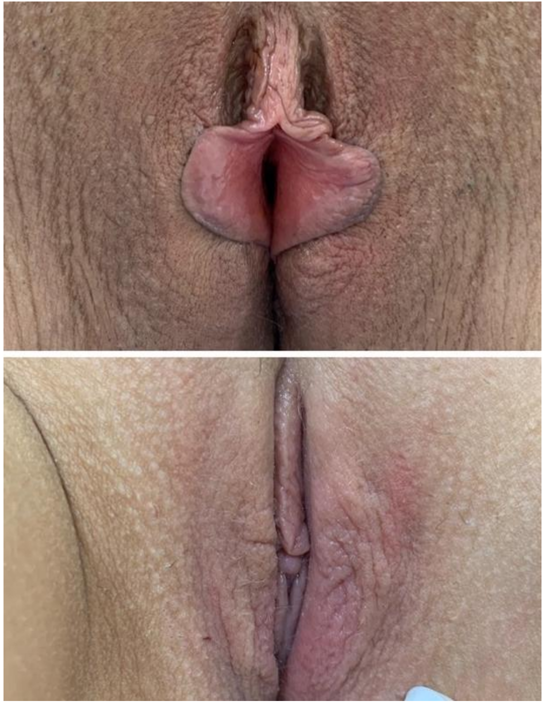
After the clamps were removed, the treated area was managed with targeted local applications of anti-inflammatory and antibiotic solutions. Specifically, Fucidin H cream, containing fusidic acid 20 mg/g and hydrocortisone acetate 10mg/g, was used in conjunction with Baneocin powder, which includes zinc bacitracin 250 UI and neomycin sulphate 500 UI/g. To control bleeding and further protect the site, a hemostatic sponge was placed over these topical agents, and the area was subsequently dressed. Pain management was addressed systemically through an intravenous administration of acetaminophen 10mg/ml, amounting to 100 ml, and an oral dose of Ketonal Forte, which contains ketoprofen at a concentration of 100 mg.

Figure 2: Excised excess labial tissue



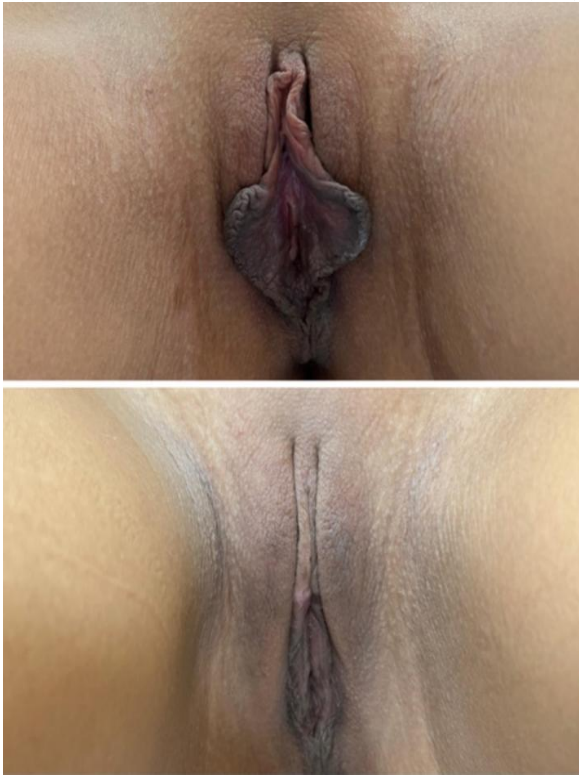
Discharge instructions provided to the patient emphasized crucial care steps to ensure proper healing. The patient was instructed to maintain local compression and restrict themselves to bed rest on the day of the procedure to minimize movement and stress at the site. For the initial three weeks post-procedure, the patient was advised to clean the area using Betadine and apply the previously mentioned Fucidin H cream and Baneocin powder twice daily. In the subsequent three weeks, the regimen shifted to cleaning with water and soap followed by the application of a protective repairing cream to foster skin restoration and barrier function.

Figure 3: Case 1. (a) Before and (b) six weeks after laser labiaplasty



At the six-week post-procedure mark, a follow-up consultation was arranged to evaluate the healing progress and the cosmetic outcome of the laser labiaplasty. The provided figures (Figure 1 and Figure 2), display the condition of the area before the procedure and at the six-week follow-up. These images illustrate a notable reduction in labial size and improved symmetry, indicating a successful aesthetic enhancement. The area appeared to be well-healed without signs of infection or significant inflammation, underscoring the effectiveness of the postoperative care regimen.

Figure 4: Case 2. (a) Before and (b) six weeks after laser labiaplasty



RESULTS

The study included 60 women aged between 19 and 52 years, with a mean age of 34.7 years. The average age at menarche was 13.1 years. Regarding reproductive history, 40% of patients were nulliparous, 35% had one pregnancy, and 25% had two or more pregnancies. Positive gynecological history, such as polycystic ovary syndrome, previous cesarean sections, or uterine fibroid removal, was present in 30% of patients. This demographic distribution indicates a diverse patient population seeking laser labiaplasty (Table 1).

Table 1: Demographic and Clinical Characteristics

Parameter	Mean (SD)	Range
Age (years)	34.7 (7.8)	19 - 52
Age at menarche (years)	13.1 (1.4)	11 - 16
Number of pregnancies	0.9 (1.1)	0 - 4
Positive gynecological history (%)	30%	N/A

SD – Standard Deviation

Aesthetic concerns were the primary motivation for 85% of patients, highlighting the significance of genital appearance in this cohort. Functional discomfort during daily activities, such as exercise or wearing tight clothing, was reported by 55% of patients. Discomfort during sexual intercourse affected 45%, indicating that labia minora hypertrophy can significantly impact sexual function. Recurrent infections or hygiene difficulties were less common but still noteworthy at 15% (Table 2).

Table 2: Preoperative Motivations

Motivation	Number of Patients (%)
Aesthetic concerns	51 (85%)
Functional discomfort during activities	33 (55%)
Discomfort during sexual intercourse	27 (45%)
Recurrent infections/hygiene issues	9 (15%)

Postoperative complications were minimal. Mild bleeding occurred in 10% of patients, resolving within an average of 2.3 days without intervention. Mild to moderate discomfort was experienced by 25% of patients, lasting approximately 4.2 days. Notably, statistical analysis revealed a significant association between previous pregnancies and postoperative discomfort ($p=0.03$), suggesting that multiparous women may experience more discomfort due to tissue changes from childbirth. No infections or hematomas were reported, indicating a favorable safety profile (Table 3).

Table 3: Postoperative Complications and Recovery

Complication	Number of Patients (%)	Duration (Days)	p-value
Mild bleeding - Total	6 (10%)	2.3 (1.1)	0.12
Mild to moderate discomfort – Nulliparous	6 (10%)	4.0 (1.5)	-
Mild to moderate discomfort – One pregnancy	5 (8.3%)	4.1 (1.6)	-
Mild to moderate discomfort – Multiparous	4 (6.7%)	4.5 (1.8)	0.03*
Infection	0 (0%)	N/A	N/A
Hematoma	0 (0%)	N/A	N/A

* *Student's t-test*

Table 4 provides a comprehensive overview of patient satisfaction following laser labiaplasty, as measured by the standardized Global Aesthetic Improvement Scale (sGAIS). The table categorized patient responses into five distinct levels, highlighting the overwhelmingly positive feedback received. Specifically, a majority of 33 patients, accounting for 55% of the total surveyed, reported a "Very significant improvement" in their condition, with an sGAIS score of 5. This indicated that these patients perceived the results of their surgery as greatly surpassing their expectations in terms of both aesthetic appeal and functional benefits. Additionally, 22 patients, representing 37% of the total, observed a "Significant improvement," scoring a 4 on the sGAIS. This suggests that for a large number of patients, the procedure substantially met their initial goals and resulted in marked enhancements.

On the lower end of the scale, 5 patients, making up 8% of the total, felt they had only "Moderate improvement," denoted by a score of 3 on the sGAIS. This group perceived the changes as noticeable but not as extensive as perhaps hoped for. Importantly, the table showed that no patients reported a lack of change or a worsening of their condition post-procedure, with zero reports in both the "No change" and "Worsened condition" categories (scores of 2 and 1, respectively). This absence of negative feedback underscored the effectiveness and safety of laser labiaplasty in achieving desired outcomes without adverse effects. The data clearly demonstrated a high level of patient satisfaction overall, with 92% of participants rating their improvement as significant or very significant, highlighting the procedure's ability to meet or exceed patient expectations in the vast majority of cases.

Table 4: Patient Satisfaction (sGAIS Scores)

Satisfaction Level	No/Mild Complications n (%)	Moderate Complication n (%)	Total	p-value*
Very Significant Improvement	32 (97%)	1 (3%)	33	
Significant Improvement	16 (73%)	6 (27%)	22	
Moderate Improvement	0 (0%)	8 (100%)	5	
p-value				<0.001

* *Chi-square test*

Among 60 patients, 34 who were satisfied and 17 who were less satisfied cited aesthetic concerns, against expected counts of 37.4 and 13.6, respectively. Functional discomfort during activities was reported by 28 satisfied and only 5 less satisfied patients, compared to expected figures of 24.2 and 8.8. For discomfort during sexual intercourse, 20 satisfied and 7 less satisfied patients were recorded, versus an expected count of 19.8 for satisfied and 7.2 for less satisfied. Lastly, recurrent infections or hygiene issues were less commonly reported, with 6 satisfied and 3 less satisfied patients, aligning closely with expected values of 6.6 and 2.4. The overall chi-square analysis resulted in a p-value of 0.306, indicating no significant statistical association across the groups (Table 5).

Table 5: Analysis of Complaints and Patient Satisfaction Post-Laser Labiaplasty

Complaint Type	Satisfied Patients (n = 40, %)	Less Satisfied Patients (n = 20, %)	Expected (Satisfied)	Expected (Less Satisfied)	p-value
Aesthetic concerns	34	17	37.4	13.6	
Functional discomfort during activities	28	5	24.2	8.8	
Discomfort during sexual intercourse	20	7	19.8	7.2	
Recurrent infections/hygiene issues	6	3	6.6	2.4	
p-value					0.306

Patients with Type III hypertrophy showed a substantially higher improvement in sexual discomfort ($p < 0.001$), aligning with their higher baseline rates of dyspareunia. Differences in aesthetic and functional improvements were not statistically significant across the three groups ($p = 0.43$ and $p = 0.07$, respectively), although Type II and Type III trended toward slightly greater gains than Type I. Reduction in hygiene-related complaints was similar among all types ($p = 0.73$). Overall satisfaction (sGAIS) remained high across all groups, with no statistically significant variation ($p = 0.56$), as presented in Table 6.

Table 6: Postoperative Quality of Life Differences by Labial Hypertrophy Type

Variable	Type I	Type II	Type III	p-value
Mean Improvement in Aesthetic Concerns (0-10 scale, higher = greater improvement)	4.7 ± 1.3	4.9 ± 1.1	5.1 ± 1.2	0.43
Mean Improvement in Functional Discomfort (0-10 scale)	5.4 ± 1.3	6.2 ± 1.4	6.3 ± 1.6	0.07
Mean Improvement in Sexual Discomfort (0-10 scale)	3.3 ± 1.0	4.6 ± 1.2	6.6 ± 1.5	<0.001
Patients Reporting Fewer Hygiene Issues (n, %)	2 (28.6%)	4 (23.5%)	10 (27.8%)	<0.001
Mean Postoperative sGAIS Score (1-5 scale*)	4.4 ± 0.5	4.3 ± 0.6	4.5 ± 0.4	0.56

** Standardized Global Aesthetic Improvement Scale (SGAIs): 1 – Worsened; 2 – No Change; 3 – Moderate Improvement; 4 – Significant Improvement; 5 – Very Significant Improvement.*

DISCUSSION

Literature findings

The study demonstrates that laser labiaplasty is a safe and effective minimally invasive procedure for treating labia minora hypertrophy. The high patient satisfaction rates align with existing literature, indicating that laser techniques offer significant advantages over traditional surgical methods. The predominance of aesthetic concerns as a motivation reflects societal trends emphasizing genital aesthetics and their impact on women's self-esteem and sexual health.

The low incidence of postoperative complications, such as bleeding and discomfort, highlights the safety profile of laser labiaplasty. The precise excision and coagulative properties of the CO_2 laser reduce intraoperative bleeding and eliminate the need for sutures, contributing to faster healing and reduced postoperative pain. The absence of infections and hematomas in our cohort further supports the procedure's safety.

The significant association between previous pregnancies and increased postoperative discomfort may be attributed to changes in tissue elasticity and sensitivity resulting from childbirth. This finding suggests that multiparous women may require additional preoperative counseling and postoperative support to manage expectations and enhance recovery.

In the realm of female genital cosmetic surgery, the studies by Pardo et al. [21] and Bizjak-Ogrinc et al. [22] provide valuable insights into the efficacy and patient satisfaction associated with different techniques of laser labiaplasty of the labia minora. Pardo et al. [21] reported on 55 cases conducted between October 2003 and November 2004, where the primary indications were moderate hypertrophy and labial asymmetry, with 67% of cases due to these reasons. They noted a high satisfaction rate, with 91% of patients reporting being very satisfied and 9% satisfied, despite a 7% incidence of minimal suture dehiscence during the early postoperative period. In a similar manner, the study by Bizjak-Ogrinc et al. [22], which analyzed 80 patients from February 2015 to April 2018, found an equally high level of patient satisfaction with the sutureless laser labiaplasty technique. Their approach, interestingly, reported minimal side effects—7 instances of wound infection, and one case each of bleeding and hematoma formation, yet no patients were partly satisfied or dissatisfied. sutures.

Similarly, Li et al.'s study on 17 Chinese women, with an average age of 36.4 years, demonstrated significant improvements in vulvar texture and pigmentation after three treatment sessions, with a scoring system showing substantial changes ($p < 0.05$) and no adverse reactions [23]. Patients self-reported enhanced satisfaction, indicating both perceived and observed effectiveness. Similarly, Lauterbach et al. [24] assessed vaginal CO_2 laser treatment in a cohort of 25 women with sexual dysfunction and pelvic floor issues. They reported significant increases in vaginal elasticity and tightening post-treatment (54.8 ± 5.2 vs. 41.5 ± 6.3, $P = 0.0027$; 1.97 ± 0.25 vs. 1.32 ± 0.31, $P = 0.0014$), as well as improvements in pelvic muscle contraction strength (25.9 ± 3.5 vs. 16.5 ± 4.2, $P = 0.0011$) and FSFI and VHI scores. This study utilized vaginal tactile imaging (VTI) for objective assessment, adding robust quantification to support the clinical effectiveness of CO2 laser treatment in enhancing vaginal biomechanical properties.

Moreover, Messas et al. [25] reviewed 40 studies involving 3466 participants to assess the efficacy of fractional CO_2 ($FrCO_2$) laser therapy in treating genitourinary syndrome of menopause (GSM) and vulvovaginal atrophy (VVA) [25]. Their findings highlight the therapy's good efficacy and safety, with high patient satisfaction noted across studies. However, they also pointed out the lack of level I evidence and called for more randomized, sham-controlled trials to validate these results further and address clinical questions such as cost-effectiveness and potential synergistic effects with other treatments. Similarly, Géczi et al. [26] conducted a systematic review and meta-analysis of various labiaplasty techniques, analyzing data from 86 studies. They reported a high overall satisfaction rate (94%, CI 93%-95%) with specific techniques like deepithelialization, reaching even higher satisfaction rates (97%, CI 85%-99%). Despite these high satisfaction rates, they noted variations in complication rates across different techniques, with some, like the wedge resection, showing higher incidences of complications such as dehiscence. Both studies underscore the importance of personalized treatment approaches and the need for high-quality research to optimize outcomes in cosmetic genital surgeries.

The study by Smarrito et al. [27] provided a focused examination of secondary labiaplasties, reporting on 44 cases split into two main categories: those involving wound dehiscence primarily from lambda laser procedures and those related to over-resections or amputations. The authors highlighted the use of local flaps and lipofilling techniques to address aesthetic and functional issues resulting from over-resection, emphasizing the importance of surgical precision and anatomical knowledge to prevent such complications. In a similar manner, the systematic review and meta-analysis by Escandón et al. [28] surveyed a much larger cohort of 3804 patients across 46 studies, reporting a high satisfaction rate of 99% for labia minoraplasty. However, they also noted significant complications, such as a 5% incidence of dehiscence from laser-assisted labiaplasty and up to 8% hematoma formation from W-shape resection. Both studies underscore the necessity of thorough training in surgical techniques and patient-specific approaches to optimize outcomes and minimize the need for subsequent corrective procedures. The findings from Escandón et al. [28] further support the observations of Smarrito et al. [27] by quantitatively demonstrating the impact of technique selection on complication rates and patient satisfaction, thereby reinforcing the call for meticulous surgical practice and adequate anatomical understanding in labiaplasty procedures.

Limitations

This study has several limitations. While the study provides valuable insights, limitations include its retrospective design and the reliance on patient-reported outcomes, which may introduce bias. The lack of a control group undergoing traditional surgical labiaplasty limits direct comparison of efficacy and safety between techniques. The retrospective design may introduce selection bias, as only patients who returned for follow-up were included. The sample size, while larger than some previous studies, is relatively small and may not represent the broader population. Reliance on subjective measures like the sGAIS may not capture objective functional improvements. Additionally, the absence of a control group limits the ability to compare laser labiaplasty directly with traditional surgical methods. Future prospective, randomized studies with larger sample sizes are warranted to validate these findings and optimize patient selection and procedural protocols.

CONCLUSION

Laser labiaplasty is an effective and safe, minimally invasive procedure for women seeking labia minora reduction due to aesthetic or functional concerns. The high patient satisfaction rates and low incidence of complications make it a valuable alternative to traditional surgical techniques. Personalized patient counseling and careful consideration of individual medical histories can further enhance outcomes. Future research should focus on long-term results and direct comparisons with other surgical modalities to establish standardized guidelines.

Conflicts of interest and sources of funding

The authors declare no conflict of interest. No artificial intelligence automatically generated text was inserted in this manuscript, and no image was previously published in another journal or is under consideration of being published elsewhere. This research received no external funding.

Authors' contribution

Local treatment options for management of loco-regional esophageal squamous cell carcinoma

Tülay Eren[1], Gökşen İ. İmamoğlu[1], Fatih Yildiz[2], Süheyla A. Arslan[3], Sultan A. Kocacan[1], Salih Z. Çakar[4], Ozan Yazici[4], Doğan Yazılıtaş[1], Nuriye Özdemir[3], Berna Öksüzoğlu[2]

Abstract: *Aim: Surgical treatment is the main treatment method for esophageal cancer. The prognosis is poor due to high local recurrence and distant metastasis rates. Study aims to evaluate the most effective local treatment modality esophageal squamous cell carcinoma (SCC) according to real life data.*

Method: 136 patients were studied retrospectively. All patients were middle or lower esophageal cancer and had the SCC histology. Patients were divided into the surgical resection, definitive CRT (dCRT), and multimodal treatment groups according to curative local treatment they received.

Result: 32.4% were in the surgical, 36% were in the dCRT, and 31.6% were in the multimodal group. Median disease-free survival was 21 months (95% CI 14-27) in the surgical group, 8 months (95% CI 4-11) in the dCRT group, and 18 months (95% CI 0-39) in the multimodal group (p=0.059). The median overall survival was found to be 40 months (95% CI 0-92) in the surgical group, 19 months (95% CI 15-22) in the dCRT group, and 54 months (95% CI 11-96) in the multimodal group (p=0.012). In multimodal group, the number of patients receiving preoperative CRT was 25, and postoperative CRT was 18. Median OS was 47 months (95% CI 0-99) in the preoperative CRT group, and 64 months (NA) in the postoperative CRT group (p=0.302).

Conclusion: DFS and OS contributions of multimodal treatment in esophageal SCC have been shown in the present study. The addition of CRT to surgery in the preoperative or postoperative period has a contribution independently of the treatment sequence.

Keywords: *multimodal treatment, surgery, definitive chemoradiotherapy, squamous cell, esophagus cancer*

INTRODUCTION

Esophageal cancer is the seventh most common cause of cancer-related deaths worldwide. In 2012, 455,800 people were diagnosed with, and 400,200 people died from esophageal cancer [1].

Surgical resection has traditionally been the primary treatment for esophageal cancer in order to maintain local disease control and prolong life expectancy. The median survival is 15-18 months, and the 5-year survival rates are 20-25% after esophagectomy [2].

Failure in the treatment is generally due to recurrence and metastases. Developments in standard therapy are ongoing. Radiotherapy can provide locoregional control in esophageal cancer, while chemotherapy has both local and systemic antineoplastic effects. With the development of multidisciplinary treatment approaches, the use of

chemoradiotherapy (CRT) in addition to surgery has become the most frequently used treatment method [3].

In esophageal cancer treatment, the results obtained from surgical treatment alone are not satisfactory in terms of locoregional recurrence or distant metastasis rates. This has paved the way for multimodal treatment approaches. Together with the multimodal treatment, chemoradiotherapy (CRT) added to surgery in the preoperative or postoperative period, aims to provide disease-free survival and an increase in life expectancy.

Preoperative chemoradiotherapy has begun to be used to increase the R0 resection rates by reducing the tumor stage before surgery, thereby contributing to survival [4-10]. The application of surgery after preoperative chemoradiotherapy is now a well understood and effective treatment [11, 12]. In the ChemoRadiotherapy for Oesophageal cancer followed by Surgery Study (CROSS), a pilot study related to preoperative chemoradiotherapy, the preoperative chemoradiotherapy was reported to increase the median OS approximately 2-fold when compared to surgical treatment alone (49.4 vs 24.0 months) [4].

In the literature, there are data about the postoperative (adjuvant) activity of chemo-radiotherapy in addition to its preoperative activity. In the past, the major problem in applying chemoradiotherapy in the postoperative period was the inability of patients to complete the scheduled treatment due to poor performance of the patients after surgery, but currently developing surgical and radiotherapy techniques have partly removed this problem. Studies by Rice et al. [13] and Bedard et al. [14] have demonstrated the survival advantage of postoperative CRT. In the retrospective study by Rice, the median survival was stated to be 28 months with surgical postoperative CRT, and 15 months with surgery alone ($p<0.05$). In the study by Bedard, the median overall survival was reported to be 47.5 months with postoperative CRT and 14.1 months with surgery alone ($p=0.001$) [14].

Following the studies showing the benefits of preoperative and postoperative chemoradiotherapy, studies about treatment sequence emerged. Current data on the prognostic effect of local treatment sequence in esophageal cancer remain controversial [15, 16]. In a study based on the SEER data, it was determined that preoperative CRT ensured better survival compared to postoperative CRT [15], while a prospective study reported no difference in survival between taking the CRT in the preoperative or postoperative period [16].

In the light of this information, the prognostic implications of optimal multimodal treatment, surgery and chemoradiotherapy sequence in the treatment of esophageal cancer are still controversial. No standard guideline has been created in this particular. The main aim of this study was to evaluate the most effective local treatment modality in non-metastatic, middle and lower esophageal squamous cell carcinoma (SCC) according to real-life data.

METHODS

A total of 136 patients diagnosed between the years 2005-2016 in 3 different oncology clinics were included in the study. The patient data were reviewed retrospectively. Patients aged 18-70 years, without distant metastasis, treated for curative purposes, with ECOG performance status 0-2, with appropriate liver/renal reserve, middle and lower esophagus involvement, and with SCC histology were included in the study. Patients with adenocarcinoma histopathology, with cervical esophagus involvement, and those who only received RT as a local treatment were not included in the study.

All the patients were applied with thorax and entire abdomen computed tomography (CT) or positron emission tomography (PET-CT) or endoscopic ultrasonography (EUS) examinations for the purpose of staging prior to local treatment. The patients were divided into 2 groups as local and local advanced disease according to the radiological results at the time of diagnosis. Radiologically, patients with T4 tumors or lymph node positivity were considered to have locally advanced disease, while non-T4 patients with lymph node-negativity were considered to have local disease.

The patients were divided into 3 groups as those who underwent only surgical resection, only definitive CRT (dCRT), and multimodal treatment (preoperative CRT or postoperative CRT) according to the curative local treatments they received and were evaluated comparatively. Platinum-based combination therapies (fluorouracil or taxane) were administered concomitantly with the chemotherapy regimen in patients receiving chemoradiotherapy.

In CRT planning, a 3 mm interslice distance CT scan was performed on all patients in the supine position. In patients undergoing definitive and preoperative chemoradiotherapy, the gross tumor volume (GTV) was determined for primary mass and involved lymph nodes using thoraco-abdominal CT, PET-CT, endoscopy and EUS information, if available. The clinical target volume (CTV) was established by giving a margin of 4 cm in the superior-inferior direction and 1 cm in the radial direction to the primary mass. The planning volume was obtained by allowing 1 cm extra margin to this. The spinal cord, lungs, and organs at risk, such as the heart, remaining within the area were contoured. In postoperative therapy, bilateral supraclavicular or celiac lymph nodes were included in the area in the location of all mediastinum and primary masses.

The gastroesophageal intersection and proximal stomach were included in the area in distal localized tumors.

The radiotherapy (RT) plans were made by applying the 3-dimensional conformal technique. Patients undergoing definitive CRT (dCRT) received a total of 50.4 Gy radiotherapy, and those undergoing pre-operative or postoperative CRT received a total of 45 Gy radiotherapy, which was applied as 1.8 Gy daily for 5 days a week.

All patient records were reviewed clinically, pathologically and in terms of treatment characteristics. The long-term survival data of patients were obtained from the patient files and from the data of the Turkish civil registry office.

Approval for the study was granted by the Ethics committee of Sağlık Bilimleri University Dışkapı Yıldırım Beyazıt Training and Research Hospital.

The data were analyzed using SPSS 18.0 for Windows software. Descriptive statistics were expressed as mean ± standard deviation or median (minimum-maximum) for non-continuous numerical variables, and as number (n) and percentage (%) for categorical variables.

The progression and overall survival rates of all cases were investigated using Kaplan-Meier survival analysis. The 2-year and 3-year cumulative progression and overall survival rates together with mean lifespan and 95% confidence intervals for these terms were calculated. The demographic characteristics of the patients were assessed using descriptive statistical methods. Parameters that were significant in univariate analysis were assessed using Cox regression multivariate analysis. A value of p<0.05 was accepted as statistically significant.

RESULTS

A total of 136 patients were evaluated comprising 32.4% (n=44) in the surgical group, 36% (n=49) in the definitive CRT (dCRT) group, and 31.6% (n=43) in the multimodal treatment group. Of the total patients, 52.2% were female and 47.8% were male.

The demographic characteristics of the patients are shown in Table 1.

Table 1: Demographic characteristics of the patients

		Surgery (n=44)	**dCRT** (n=49)	**Multimodal Treatment** (n=43)	***p* Value**
Age (years)	Median (min-max)	52 (32-76)	58 (25-77)	50 (32-70)	0.001
Gender	Female	26 (59.1%)	21 (42.9%)	24 (55.8%)	0.249
	Male	18 (40.9%)	28 (57.1%)	19 (44.2%)	
Smoking	Smokers	20 (45.5%)	26 (53.1%)	12 (39.5%)	0.426
	Non-smokers	24 (54.5%)	23 (46.9%)	26 (60.5%)	
Alcohol Use	Users	15 (34.1%)	14 (28.6%)	19 (44.2%)	0.288
	Non-users	29 (65.9%)	35 (71.4%)	24 (55.8%)	
Comorbid disease	Present	15 (34.1%)	16 (32.7%)	8 (18.6%)	0.208
	Absent	29 (65.9%)	33 (67.3%)	35 (81.4%)	
Cancer history in family	Present	9 (20.5%)	14 (28.6%)	9 (20.9%)	0.581
	Absent	35 (79.5%)	35 (71.4%)	34 (79.1%)	
Tumor Grade	Well	2 (4.5%)	5 (10.2%)	4 (9.3%)	0.240
	Moderate	8 (18.2%)	6 (12.2%)	5 (11.6%)	
	Poor	3 (6.8%)	12 (24.5%)	4 (9.3%)	
Location of tumor	Mid-esophagus	18 (40.9%)	25 (51.0%)	25 (58.1%)	0.271
	Lower esophagus	26 (59.1%)	24 (49%)	18 (41.9%)	
Pre-clinical stage	Early	26 (59.1%)	11 (22.4%)	20 (46.5%)	0.001
	Locally advanced	18 (40.9%)	38 (77.6%)	23 (53.5%)	

When the postoperative stages of 44 patients treated with surgery alone were evaluated, it was seen that 15.9% (n=7) of these patients were stage 1, 40.9% (n=18) were stage 2, and 43.2% (n=19) were stage 3. Adjuvant chemotherapy with cisplatin/fluorouracil combination was administered to 27.3% (n=12) of the patients in this group.

One patient died in the intensive care unit due to surgical complications in the postoperative period.

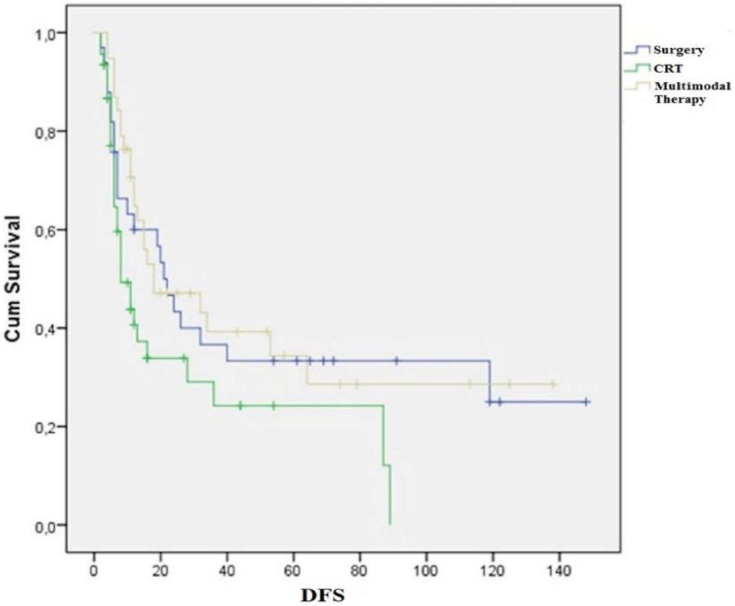
In the group of patients receiving definitive CRT, 1 patient died due to complications during treatment.

The number of patients receiving preoperative CRT was 25 and the number of patients receiving postoperative CRT was 18 in the multimodal treatment group. In the multimodal treatment group, a pathological complete response was determined in 64% (n=16) preoperative CRT group. In this group, 4 patients died in the postoperative period due to complication. In postoperative CRT group, 11.1% (n=2) of the patients were stage 1, 16.7% (n=3) were stage 2, and 72.2% (n=13) were stage 3 after surgery.

The median follow-up time was 31 months (2-142) in the surgical group, 11 months (2-106) in the definitive CRT group, and 20 months (4-140) in the multimodal treatment group.

The median disease-free survival was 21 months (95% CI 14-27) in the surgical group, 8 months (95% CI 4-11) in the definitive CRT group and 18 months (95% CI 0-39) in the multimodal treatment group (p=0.059). DFS curve shown in Figure 1.

Figure 1: Disease Free Survival



The 2-year disease-free survival (DFS) was 43% in the surgical group, 33% in the definitive CRT group, and 47% in the multimodal treatment group (p=0.05).

The median overall survival (OS) was 40 months (95% CI 0-92) in the surgical group, 19 months (95% CI 15-22) in the definitive CRT group and 54 months (95% CI 11-96) in the multimodal treatment group. The difference between the groups was statistically significant (p=0.012). Cumulative OS curve shown in Figure 2.

The 2-year OS was 68% in the surgical group, 40% in the definitive CRT group and 59% in the multimodal treatment group (p=0.01).

In the multimodal treatment group, the median OS was found to be 47 months (95% CI 0-99) in the preoperative CRT group, and 64 months (NA) in the postoperative CRT group. The difference between the groups was not statistically significant (p=0.302). OS curve when the multimodal group was divided into two as preoperative and postoperative CRT shown in Figure 3.

DISCUSSION

Surgical resection is the basic method that is conventionally effective in providing local disease control in non-metastatic esophageal cancer treatment. However, due to high locoregional recurrence and distant metastasis rates, surgical resection alone is insufficient. The median overall survival after esophagectomy is 15-18 months and the 5-year survival rate is 20-25% [2].

Figure 2: Overall Survival

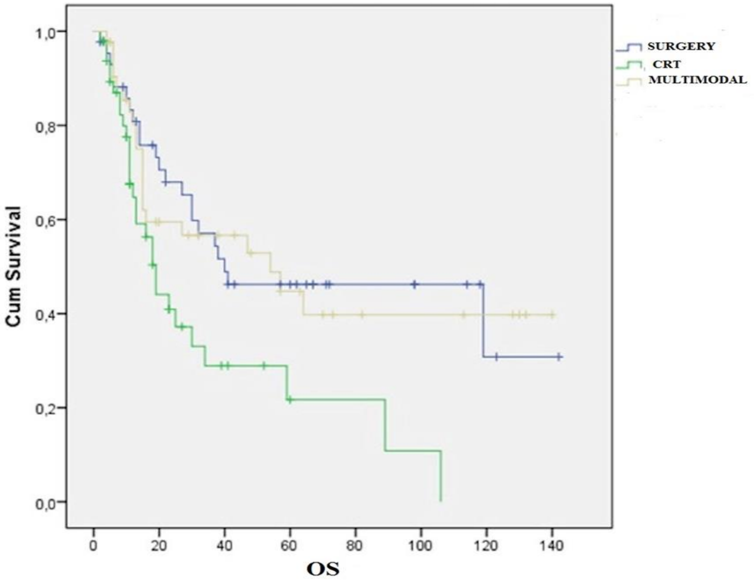


Figure 3: Overall survival in definitive chemoradiotherapy group

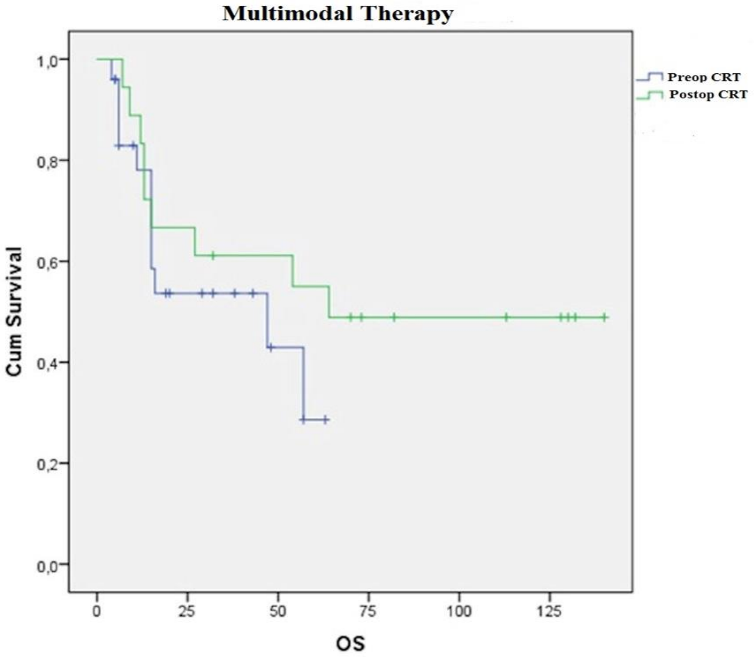

In a study by Orringer et al. conducted on 800 patients, the 5-year survival rates after esophagectomy were reported 23% [17]. In another study in which the surgery was compared with surgery after preoperative CRT, and patients were evaluated in the early stage, the median OS was reported as 18.6 months in the patients who underwent surgery [9].

In the present study, the disease-free survival was 21 months and the overall survival was 40 months in the group of patients who underwent surgery alone. In the surgical group, 27.3% of the patients (n=12) received adjuvant chemotherapy with Cisplatin/Fluorouracil combination. Compared to general literature data, the patients included in the current study had longer DFS and OS. Possible reasons for this may be the exclusion of upper esophageal tumors, which are known to have a worse prognosis, and the fact that approximately 25% of the patients who underwent surgery were administered adjuvant chemotherapy.

Although surgical resection is still the basic standard approach in non-metastatic esophageal tumors, definitive chemoradiotherapy is still an effective local treatment alternative for patients not suitable for curative surgery [18]. In one of the largest studies in which a direct comparison was made between definitive chemoradiotherapy and surgery, the two-year survival rates were 45.4% in the definitive CRT group and 56.2% in the surgical group [19]. This study supports the idea that all patients who cannot undergo surgery due to high risk may be recommended definitive chemoradiotherapy independent of the histology.

In the present study, the definitive CRT group showed a disease-free survival of 8 months, an overall survival of 19 months, and a 2-year survival rate of 43%. These results are consistent with the literature.

Although surgical resection is the curative treatment approach for esophageal cancer, the poor long-term survival outcomes have encouraged multimodal treatment approaches in this patient group. With preoperative chemoradiotherapy as one of the multimodal treatment methods, the treatment of micro metastases and regression of the tumor stage contribute positively to the overall survival rates of patients by increasing the rate of curative resection [4-10].

In the CALGB 9781 study, the median survival was 4.4 years vs. 1.7 years (p=0.002) and 5-year survival rates were reported to be 39% vs 16% in favor of multimodal treatment in esophagectomy after preoperative CRT, where the cisplatin/fluorouracil combination was used compared with esophagectomy only [10]. In the CROSS trial, patients who underwent surgery after preoperative chemoradiotherapy and patients who underwent surgery only were compared. The concomitant paclitaxel-carboplatin combination was used in this study. It was reported that the preoperative CRT improved the survival times compared to the surgery group (OS 49.4 months vs 24.0 months, HR for survival, 0.657; 95% CI, 0.495-0.871; p=0.003) [4]. The long-term results of the CROSS trial also showed that the contribution to overall survival continued [12].

Another multimodal treatment approach is postoperative adjuvant CRT. Many studies have shown the contribution to survival of postoperative chemoradiotherapy in patients who have undergone esophagectomy [13, 14, 20, 21, 22, 23]. In a study by Hwang et al., the 3-year OS rates in squamous cell esophageal cancer were 44.9% in patients who underwent postoperative CRT after esophagectomy, and 28.1% in patients who underwent surgery alone [20].

Following studies showing the contribution of preoperative and postoperative CRT in esophageal cancer, questions were asked about the prognostic contribution of surgery and the sequence of chemoradiotherapy and what should be the optimal treatment sequence. In a prospective study by Lv et al., where preoperative CRT, postoperative CRT, and surgery were compared, both 5-year OS (43.5% vs 42.3%) and 5-year DFS (37.5% vs 37.2%) were found to be similar between the preoperative CRT and postoperative CRT groups (p>0.05) [16]. Chen et al. emphasized that CRT together with surgery extended the overall survival independently of the treatment sequence [24].

In a retrospective study in which Hsu et al. evaluated the optimal treatment sequence for locally advanced esophageal cancer in 2017, the preoperative CRT and postoperative CRT groups were found to have similar median OS (26 vs 23 months, p=0.31) [25]. A statistically insignificant but clinically significant difference was found in disease-free survival (16.7 months vs 10.4 months, p=0.061). However, in that study, the rate of stage 3 patients was higher in the group receiving postoperative CRT.

Based on this information, in the present study, the multimodal treatment group was found to be superior to patients who underwent surgery only or definitive CRT in terms of both overall survival and disease-free survival. The treatment sequence in the multimodal group was not found to affect the overall survival and disease-free survival and these results are consistent with the current literature.

Since the present study was retrospective, it has some limitations. As patients from three different oncology clinics were included, it was not possible to obtain information on which criteria the patients were directed to different treatment groups when the initial treatment plan was made. No information could be obtained about why the patients with local disease could not be operated on. The fact that patients undergoing surgery were operated on by different surgical clinics was another limitation. Not all toxicity data could be obtained due to the retrospective nature of the study.

In conclusion, it was determined that the multimodal treatment of squamous cell medium and lower esophageal tumors increased the disease-free survival and overall survival, but the treatment sequence had no effect in this particular. However, there are questions that still need to be answered for operable esophageal tumors, such as what the ideal local treatment modalities and combinations are, whether it is preferable to apply the chemotherapy scheme synchronously with CRT, and the location of postoperative adjuvant chemotherapy. There is a need for further randomized phase studies on these subjects.

Abstract: Background: Nonmelanoma skin cancers (NMSCs), including basal cell carcinoma (BCC) and cutaneous squamous cell carcinoma (cSCC), often occur in high-risk areas like the face, ears, and scalp. Surgical excision is standard, but achieving tumor-free margins while preserving function and appearance is challenging. This study evaluates the adequacy of arbitrary surgical margins versus histopathological clearance. Methods: A retrospective analysis was conducted on 147 patients with BCC or cSCC in high-risk areas treated at Elias Emergency University Hospital (2020–2024). Data included demographics, tumor type, size, location, excision margins, and histological clearance. Margins were grouped from 0 mm to >10 mm. Results: Most patients were male (59.2%) with a mean age of 70.6 years. BCC accounted for 70.7% of cases. Arbitrary margins averaged 5.4 mm; mean histological margins were ~2.5 mm. Complete excision was achieved in 91.2%; positive margins were most common on the nose and scalp. Discussion: Arbitrary margins in high-risk areas are often narrower than guidelines recommend, especially where tissue is limited, increasing the risk of incomplete excision. Conclusion: While aesthetic and functional considerations often necessitate smaller margins, improved intraoperative margin assessment could enhance oncological outcomes in high-risk NMSC.

Keywords: Nonmelanoma skin cancer (NMSC), Basal cell carcinoma (BCC), Cutaneous squamous cell carcinoma (cSCC), Surgical margins, Histopathological clearance, High-risk anatomical areas, Mohs micrographic surgery, Arbitrary excision margins, Incomplete excision, Oncologic safety

INTRODUCTION

Basal cell carcinoma (BCC) and cutaneous squamous cell carcinoma (cSCC) represent the two most common forms of nonmelanoma skin cancer (NMSC), with BCC being the most prevalent malignancy globally. While BCC is characterized by slow growth and minimal metastatic risk, its potential for local destruction and disfigurement, especially in anatomically sensitive areas, underscores the importance of timely and adequate treatment. cSCC, although less frequent, poses a relatively higher risk of local invasion and lymphatic metastasis, particularly in immunosuppressed patients [1].

The cornerstone of NMSC treatment remains surgical excision, favored for its efficacy, cost-effectiveness, and accessibility across healthcare systems. Surgical excision allows for histopathological evaluation of the margins and is generally sufficient for low-risk lesions. However, for high-risk tumors located in functionally and cosmetically sensitive areas (defined as Area H: central face, ears, eyelids, nose, genitals, and hands), standard excision can be technically challenging. In these zones, even small tumors may have subclinical extension, increasing the risk of incomplete excision and recurrence [2].

A surgical margin refers to the outer edge of the tissue removed during surgery. The tumoral involvement of the resected margins is a crucial prognostic element. Evaluating the tumoral invasion of the margins is essential for determining whether the excision is sufficient or incomplete. In instances of cancer, follow-up management choices depend on whether the margins are devoid of tumors. Consequently, precise and timely margin evaluation is essential. Attaining clear surgical margins guarantees the complete removal of cancerous tissues, minimizing the chances of local recurrence [3].

While standard excision remains widely used, it has notable limitations in high-risk areas. One of the primary drawbacks is the inability to assess 100% of the peripheral

and deep margins during surgery. Mohs micrographic surgery (MMS) is considered the gold standard for treating high-risk NMSCs, particularly recurrent or infiltrative lesions. MMS provides complete circumferential and deep margin control (CCPDMA), resulting in superior cure rates—over 98% for primary BCCs and above 95% for recurrent cases. Moreover, MMS allows for maximal tissue conservation, which is crucial in cosmetically sensitive areas. However, its disadvantages include longer operative times, higher costs, and limited availability, which restrict its universal application [4].

This study aims to demonstrate that standard surgical excision can yield acceptable oncological outcomes in the management of high-risk nonmelanoma skin cancers, particularly in under-resourced hospitals where Mohs micrographic surgery is not available.

MATERIALS AND METHODS

This study included 147 patients who underwent surgical excision of non-melanoma skin cancer at the Plastic Surgery Department in „Elias Emergency University Hospital", Bucharest, Romania, between 2020-2024.

Inclusion criteria – all patients admitted to our plastic surgery department with skin lesions with high suspicion of non-melanocytic skin cancer/histopathological confirmation, in a high-risk area, who accepted the surgical treatment. The high-risk areas were defined using NCCN guidelines depending on anatomical localization and size: head, scalp, genital area, trunk, and extremities >2cm.

Exclusion criteria – patients with BCC/cSCC in low-risk areas, premalignancies, melanoma, psychological disorders, and refusal of future treatments.

Arbitrary surgical margins were defined as preoperative markings based on local tissue availability, skin elasticity, and the surgeon's experience. Data regarding sex, age, comorbidities, type of anesthesia used, type of reconstruction, surgical dissection plane, arbitrary surgical margins, peripheral and deep clean margins, tumor diameter, and ulceration were collected and analysed. Surgical standard excision was performed using a no.15 blade in a full-thickness fashion. The deep dissection plane was chosen depending on the case. Excisions were performed under local, regional, or general anesthesia. For wound closure, depending on defect size and location, we used primary closure, skin grafts, and/or flaps. Specimens were oriented using sutures as markings for histopathological evaluation. Excised specimens were sent for histopathological examination to assess tumor clearance.

The histological clearance margins of the lesions were measured peripherally and in depth, recorded in millimeters to one decimal place. They were categorized into five groups:

- zero clearance (indicating margin involvement)
- clearance under 1 mm (0.1–0.9 mm)
- clearance between 1 and 4.9 mm
- clearance between 5 and 9.9 mm
- clearance greater than 10 mm.

Those with zero clearance were advised to have a re-excision following their histopathological results. Patients with clearance margins under 1 mm underwent dermatoscopy surveillance every 3 months; in case of recurrence, the tumors were re-excised. Patients were monitored for wound healing and recurrence.

RESULTS

Demographic

In the 4 years, there were 147 patients, predominantly men with 87 cases (59.2%), with an average age of 70.6 years (see Table 1). BCCs were the predominant cancer, with 104 excisions (70.7%), while cSCCs had 43 excisions (29.3%).

Regarding comorbidities, cardiovascular diseases were predominant in 68 cases (46,2%), followed by diabetes mellitus in 11 cases (7.4%) and other malignancies in 10 cases (6.8%). The anesthesia of choice was local in 143 cases (97.3%), regional and general anesthesias were less prevalent at 2 and 3 cases, respectively. The preferred method of reconstruction was the local flap, with 54 cases (36.7%), followed by full-thickness skin grafts with 38 cases (25.9%), and direct sutures with 36 cases (24.5%). On the other hand, reconstruction techniques such as regional flaps and split-thickness skin grafts were rarely used.

The surgical plane of choice was subcutaneous with 62 cases (42.2%), suprafascial with 42 cases (28.6%), while deeper planes such as supracondylar (14.3%) and supraperiostal (8.2%) have been rarely used.

Incomplete excisions

There were 13 cases of incomplete excisions (see Table 2). The areas with incomplete excisions were located on the nose, with 5 out of 13 cases, followed by the scalp, 4 out of 13 cases. The cheek and peri-orbital regions had a lower rate of incomplete excisions, accounting for 2 cases. Notably, no incomplete excisions were recorded for lesions located on the lips, limbs, or trunk.

Table 1: Demographics and Clinical Characteristics

Sex - female - male	 60 (40.8%) 87 (59.2%)
Age	70.6 years (29 – 94 years)
Type - BCC - SCC	 104(70.7%) 43 (29.3%)
Comorbidities - CV - Diabetes Mellitus - other malignancies	 68(46.2%) 11(7.4%) 10 (6.8%)
Type of anesthesia - local - regional - general	 143 (97.3%) 2 (1.4%) 3 (2%)
Type of reconstruction - direct suture - skin graft -STSG -FTSG - local flap - regional flap	 36 (24.5%) 6 (4.1%) 38 (25.9%) 54 (36.7%) 3 (2%)
Surgical dissection plane - subcutaneous - suprafascial - supracondral - supraperiostal	 62 (42.2%) 42 (28.6%) 21 (14.3%) 12 (8.2%)
Arbitrary surgical margins (mean, mm)	5.4 mm (2-15mm)
Largest diameter (mean, mm)	21.6 mm (5 – 184mm)
Peripheral clearance margins (mean, mm)	2.52 mm (0-9.2mm)
Deep clearance margins (mean, mm)	2.65mm (0-20mm)

Table 2: Incomplete excisions expressed as % of all incomplete excisions depending on anatomic site

Anatomic site	Total Lesions	Incomplete Excisions	% of All Incomplete Excisions	Mean Diameter (mm)	Mean Arbitrary Margin (mm)	Presence of Ulceration (n)
Cheek	17	1	7.7%	17.11	4.3	16
Forehead	15	2	15.4%	18.6	4.4	9
Nose	33	5	38.5%	14.1	4.3	24
Peri-orbital	24	1	7.7%	15.45	5.2	15
Lips	8	0	0%	13.3	6.2	8
Scalp	26	4	30.8%	22.6	5.0	19
Limbs	14	0	0%	35.2	9.2	11
Trunk	10	0	0%	58.6	7.6	6
	147	**13**				

The majority of cancers (64.6%) had peripheral histological clearance margins between 1.0–4.9 mm, as we can see in Table 3. Margins with clearance under 1 mm were present in 15.6% of cases. Complete margin involvement (0 mm clearance) was identified in 4.8% of tumors, comparable to the 8.8% incomplete excision rate. No cases exceeded peripheral margins larger than 10 mm, balancing oncological safety with tissue preservation.

The most common deep margin range was 1.0–4.9 mm, present in 57.1% of cases. Deep margins between 0.1–0.9 mm were observed in 19% of cases. Complete deep margin involvement (0 mm clearance) was identified in 8.8% of cases, reinforcing the necessity of achieving adequate excision depth to minimize recurrence risk. Only 4.1% of lesions had deep clearance margins exceeding 10 mm.

Table 3: Margin Clearance Distribution Among Excised Tumors

Margins (mm)	Peripheral total	% total lesions	Deep total	% total lesions
0	7	4.8%	13	8.8%
0.1-0.9	23	15.6%	28	19.0%
1-4.9	95	64.6%	84	57.1%
5.0-9.9	13	8.8%	16	10.9%
>10	0	0%	6	4.1%

Peripheral Margins >1 mm

The highest histological clearance rates, with peripheral margins over 1 mm, were noted in lesions located on the limbs (100%) and scalp (73%), suggesting that these regions allow a wider excision. In contrast, the lowest rates of peripheral clearance beyond 1 mm were documented in lesions on the forehead (6.1%) and lips (4.8%), revealing the technical difficulties of obtaining wider margins in these areas.

Table 4: Distribution of Peripheral and Deep Histological Clearance Margins depending on anatomic site

Anatomic site	Total lesions	Peripheral histological clearance margins > 1mm	%	Deep histological clearance margins (0.5-4.9 mm)	%
Cheek	17	13	8.8%	17	11.6%
Forehead	15	9	6.1%	11	7.5%
Nose	33	21	14.3%	27	18.4%
Peri-orbital	24	16	10.9%	22	15.0%
Lips	8	7	4.8%	8	5.4%
Scalp	26	19	12.9%	21	14.3%
Limbs	14	14	9.5%	13	8.8%
Trunk	10	8	5.4%	10	6.8%
	147	**107**	**72.8%**	**129**	**87.8%**

Deep Margins (0.5–4.9 mm)

The nasal region had the greatest number of cases with deep margins in the 0.5-4.9 mm range, with 27 cases (18.4%), as seen in Table 4, explaining its elevated rate of incomplete excisions. Areas such as the peri-orbital region, presented 22 cases (15.0%), the scalp with 21 cases (14.3%), reveal the difficulties of achieving sufficient deep margins in said locations.

DISCUSSION

Basal cell carcinoma is the most prevalent cancer, presenting with a slow growth rate and a very low metastatic risk, located predominantly on the head and neck, but also on the limbs and trunk [5]. BCCs tend to be locally destructive and may cause deformity or recurrences if not fully excised [6]. The most important risk factor is long-term/chronic sun exposure, followed closely by a history of either BCC or SCC, with patients being more likely to develop another BCC compared to patients without a history of NMSCs. The rate of developing BCC increases with age, with an average age of 68 years; men have higher rates of BCC than women [7]. The treatment of choice is removing the tumor through different methods, such as Mohs micrographic surgery, peripheral and deep en face margin assessment, cryosurgery, electrodesiccation, and surgical excision. Surgical excision remains the staple method of removing the tumor [8,9].

Cutaneous squamous cell carcinoma, while not as prevalent as BCC, is still a frequent malignancy with similar risk factors as the BCC, such as sun exposure, Fitzpatrick skin types I-II, male gender, and other etiologies such as immunosuppression and chronic wounds (e.g., Marjolin Ulcer). Regarding the recurrence rate following surgical excision, cSCCs located in areas prone to prolonged sun exposure yielded a higher rate of recurrence compared to areas with less sun exposure. The primary risk of recurrence is invasion of the dermis. On the other hand, there was no noticeable difference between the 2 areas regarding the rate of metastases [10,11]. SCCs pose a low metastatic risk, the preferred metastatic site being the lymph node [12,13]. They can be more aggressive than BCCs, with a higher likelihood of local invasion and potential for metastasis, especially in high-risk cases. Understanding the local invasiveness of NMSCs is crucial for determining appropriate treatment strategies and improving patient outcomes [14].

Surgical excision of NMSCs aims to completely remove the tumoral tissue while sacrificing as little normal tissue as possible. This can be achieved through simple elliptical excision. However, Mohs micrographic surgery is the gold standard for treating high-risk tumors. Its primary benefit lies in conserving healthy tissue, preserving anatomical structures, and ensuring tumor-free margins. A recent randomized clinical trial found that Mohs surgery yielded superior outcomes for recurrent BCC compared to direct excision, although no significant differences were observed for primary BCC treatment [15].

Area H refers to high-risk regions, including the central face, ears, genitals, and hands, which require balancing oncologic control with cosmetic and functional outcomes [16]. Mohs surgery is an excellent option for preserving function and enhancing cosmetic outcomes. From a reconstructive perspective, imaging techniques help to identify optimal blood supply for flaps, minimizing complications and improving success rates. As a result, the focus of skin cancer surgery has evolved from simple excision and flap coverage to superior functional and aesthetic outcomes [17].

Peripheral and deep en face margin assessment (PDEMA), also known as complete circumferential peripheral and deep margin assessment (CCPDMA), is associated with the highest cure rates for NMSCs, due to complete peripheral and deep margin visualization, and re-excision of residual tumor [18]. Mohs is the most common method of PDEMA; however, there are also other techniques, such as the Tubingen method, which differs from Mohs by having a histopathological examination in a 1-5 day interval over Mohs's rapid frozen section and interpretation [19].

The mean age of patients with NMSCs in our study was 70.6, with a tendency to be more represented in males. Ciążyńska et al. observed no significant differences between genders. However, the mean age of men in their group was 70.9 +/- 11,4 years, and for women 71.4 +/- 11.9 years [20].

According to NCCN Guidelines Version 2.2025, high-risk criteria for both BCCs and cSCCs are: tumor diameters >= 2 cm in the trunk and extremities, any size pertaining to the head, neck, feet, pretibial and anogenital area, recurrence, immunosuppression, and poorly defined borders [21,22].

The issue with arbitrary surgical margins is that they can lead to either removing more normal tissue than necessary or less than required, and thus leading to recurrence. A study from the Hospital Universitari Vall d'Hebron in Barcelona reviewed histopathological reports from all BCCs treated by different specialties, aiming to determine the influence of a surgical specialty on assessing and excising a tumor with proper safety margins. It revealed that dermatologists had the lowest rate of positive margins out of other specialties, such as plastic surgery, general surgery, etc. attributed to their broader knowledge and expertise in evaluating tumor margins macroscopically. Therefore, proper identification of macroscopic tumoral margins for excision must be emphasized [23].

Australian Journal of Plastic Surgery conducted a study in which they monitored subjects with different levels of experience, as they were drawing a 3 mm, 5 mm, and 10 mm margin around different lesions without using a measurement device, with acceptable margins being considered to be approximately within 0.5 mm of the recommended surgical margin. Margins were underestimated, no matter the level of experience, being smaller in size for each bracket. Margins of 3 mm have been the most accurately estimated out of the 3, increasing the margin size leads to an increase in inaccuracy. This serves to enforce the importance of proper safety margins and the risk of re-excisions caused by improper measurements [24,25].

The majority of excised tumors (64.6%) displayed peripheral histological clearance margins ranging between 1.0–4.9 mm. Narrow peripheral margins (0.1–0.9 mm) have been observed in 15.6% of cases. Complete margin involvement (0 mm clearance) was identified in 4.8% of tumors. No cases exceeded peripheral margins larger than 10 mm, balancing oncological safety with tissue preservation. The most common deep margin range was 1.0–4.9 mm, present in 57.1% of cases. Deep margins between 0.1–0.9 mm were observed in 19% of cases. Complete deep margin involvement (0 mm clearance) was identified in 8.8% of cases, reinforcing the necessity of achieving adequate excision depth to minimize recurrence risk. Only 4.1% of lesions had deep clearance margins exceeding 10 mm. Khalid-Raja M. suggested identifying the peripheral margin of excision by using the wet blotting technique and applying a 4-mm margin of excision to all NMSCs. Their results showed a 95% successful excision rate and a peripheral clearance margin of 0.1-14 mm, a mean peripheral margin of 3.73 in the case of BCCs, and a 96% successful excision rate with peripheral margins varying from 0.5 to 19.0 mm, a mean peripheral margin of 4.86. Comparatively, our study showed a 92% successful excision rate and a mean peripheral margin of 2.52 mm, with the mean average surgical margin being 5.4 mm. The highest number of incomplete excisions was located at the nose and scalp with arbitrary surgical margins of 4.3 and 5.0 mm, respectively. Lesions over 2 cm lead to a 91.2% complete excision with a 4 mm margin while using the wet blotting technique. This coincides with our findings [26,27].

J Kiely et al. recommend the excision of poorly differentiated cSCCs with a minimum peripheral margin of 6 mm, well-differentiated cSCCs were excised with an average peripheral margin of 4.72 mm, and the poorly differentiated ones with an average margin of 6.42 mm. This led to an involvement of peripheral margins in 3% of well-differentiated lesions and 13.2% of poorly differentiated ones. Deep margins were also close or involved in 50% of poorly differentiated cSCCs, demonstrating that poorly differentiated cSCCs are not properly excised in both peripheral and deep planes, in spite of the guidelines [28].

Australian Journal of General Practice recommends for high-risk lesions over 5 mm margins for BCCs and a 6 mm margin for cSCCs, claiming selection of surgical margin should aim to balance between incomplete excision of the tumor and normal tissue sacrifice, affecting cosmetic and functional outcomes [29].

Eva Van Loo et al. found the recommended excision margins for BCC too defensive, evaluating the Dutch Guideline, which states that the margin for low-risk BCC should be 3-4 mm, and the high-risk BCC up to 20 mm, incorporating the H-zone as a high-risk BCC. Currently, the Dutch and European consensus is that high-risk BCC should have a minimum of 5 mm, or 5-15 mm (European guideline). The findings indicate that adherence to the guideline in high-risk BCC was not adequate, yet it had a limited effect on the incomplete excision rate. A margin of 3 mm was sufficient for 99.6% of low-risk BCCs, and a 5 mm margin for high-risk BCCs up to 94% [30].

High incomplete excision rates (8.8%) suggest that in certain areas, such as the nose and scalp, wider margins might be needed. The lowest incomplete excision rates were found in the peri-orbital region and the cheek, while no incomplete excisions were documented on the lips, trunk, and limbs. Ceder H found higher incomplete excision rates located on the face and scalp, the highest ones being on the nose, ear, and peri-orbital area; also noteworthy, circular excisions were also more often incomplete compared to elliptical excisions [31].

Despite its high cure rates and tissue-sparing advantages, Mohs micrographic surgery (MMS) presents several notable disadvantages that limit its universal application. One of the primary concerns is the limited availability of specialized centers and trained personnel, making access difficult in under-resourced or rural healthcare settings. MMS is also more time-consuming than standard excision, as it involves intraoperative histological analysis of multiple tissue layers, requiring patients to remain in the facility for extended periods. Additionally, the procedure is costlier due to the need for specialized equipment and trained histopathologists, potentially placing a financial burden on healthcare systems and patients alike. From a logistical standpoint, not all lesions are suitable for MMS—tumors with extensive subclinical spread, poorly defined borders, or aggressive histologic subtypes may require complementary or alternative approaches. Lastly, in settings where rapid frozen-section pathology is not feasible, delays in diagnosis and treatment can occur, reducing the practicality of MMS outside high-volume dermatologic surgery centers [32]. While Mohs surgery offers excellent cure rates, its use in elderly patients requires careful consideration. The prolonged procedure time, need for patient immobility, and potential for postoperative care challenges may be poorly tolerated by those with comorbidities or cognitive impairment. Therefore, treatment should be individualized based on the patient's overall health, functional status, and life expectancy [33].

CONCLUSION

This study highlights the challenges of achieving adequate surgical margins in high-risk anatomical areas affected by nonmelanoma skin cancers. Although arbitrary margins based on surgeon experience averaged 5.4 mm, histopathological evaluation revealed that a significant number of excisions had suboptimal peripheral or deep clearance, particularly in constrained areas like the nose and scalp. Despite a 91.2% overall rate of complete excision, the 8.8% rate of positive margins underscores the limitations of visual and tactile margin estimation alone. The findings support existing guidelines recommending wider margins ≥5 mm for BCC and ≥6 mm for cSCC, while also emphasizing the need to balance oncologic safety with aesthetic and functional preservation. In high-risk regions, individualized surgical planning, improved intraoperative margin assessment, and consideration of techniques like Mohs micrographic surgery in selected cases may optimize outcomes and minimize recurrence. Ultimately, refining margin estimation and tailoring surgical strategy to both tumor characteristics and anatomical context are essential for improving the quality of care in patients with high-risk NMSCs.

Conflicts of interest and sources of funding

The authors declare no conflict of interest. This research received no external funding.

Acknowledgments: *The authors would like to acknowledge the support of Elias University Emergency Hospital for providing access to patient data and facilitating the conduct of this study. We are also grateful to the patients who consented to participate and whose contributions were essential to this research.*

Abstract: The rise of antimicrobial resistance poses a significant challenge to global health. This study investigates the antimicrobial properties of Taraxacum officinale and Chelidonium majus. Taraxacum officinale, commonly known as dandelion, has been utilized for centuries in traditional medicine for its various therapeutic benefits, including treating cholecystitis, enhancing hepatic function, regulating blood pressure and cholesterol levels, and exhibiting diuretic effects. Additionally, research has indicated that infusions derived from this plant offer favorable outcomes in managing renal diseases. This study aims to assess the antimicrobial activity of extracts from Taraxacum officinale and Chelidonium majus employing qualitative screening, quantitative determination, and in vitro evaluation of anti-biofilm properties. In vitro evaluation of the antibiofilm activity of plant products revealed their ability to inhibit the development of biofilms on inert substrate; plant extracts of C. majus were found to inhibit biofilm formation in all bacterial strains tested, while tincture of T. officinale showed very good activity on gram-negative and fungal strains. The results obtained are promising, supporting further research into the biochemical characteristics of these extracts in order to formulate strategies for the control of bacterial and fungal infections in humans.

Keywords: extracts, antimicrobial effect, antibiofilm, Taraxacum officinale, Chelidonium majus

INTRODUCTION

The modern era of antimicrobial chemotherapeutics began with the discovery of sulfonamides and penicillin, and in the following decades the spectrum of antimicrobial substances was broadened by the discovery of new active substances capable of preventing and/or treating infections caused by pathogenic microorganisms. Thus, the introduction of antibiotics was a crucial moment that underpinned the saving of millions of patients, while at the same time leading to significant advances in medicine [1].

However, less than a decade after the clinical use of antibiotics, as a result of inappropriate prescribing or overuse of antibiotics both in humans and in veterinary and zootechnical medicine, without certainty of the infectious agent determined by laboratory tests or to promote animal husbandry [2], the gains from the development of this treatment are threatened by increasing rates of pathogen resistance to antibiotics, now leading to the Antimicrobial Resistance Crisis (AMR) [3].

The global increase in the incidence of infectious diseases that can no longer be eradicated with the substances developed to date represents the evolving response of microorganisms to the widespread administration of antibiotics. It has been declared by multiple organizations, such as the World Health Organization (WHO),

to be a public health problem of concern. Therefore, the AMR crisis has led to the need to investigate and discover new potential antimicrobial agents [4,5,6].

A new research direction is to exploit the antimicrobial properties of large varieties of medicinal plants, which represent a natural reservoir providing many compounds useful in the fight against multidrug-resistant microorganisms [7,8].

Taraxacum officinale (dandelion), is a medicinal plant that has been used for centuries for its benefits in the treatment of conditions such as cholecystitis, improving hepatic function, lowering blood pressure and blood cholesterol levels, or for its diuretic effect. In addition, studies in the literature have shown that infusions made from this plant have beneficial effects on renal diseases [8].

Chelidonium majus (celandine), one of the oldest and most widely used plants in traditional medicine, presents manyfold benefits, being often used in the treatment of eczema and condyloma caused by Human Papilloma Virus (HPV) infection, hepatic and gastric diseases, as well as having anti-inflammatory and analgesic effects. [9,10,11,12,13,14,15].

The aim of this work is to study the antimicrobial activity of extracts of Taraxacum officinale (tincture), Chelidonium majus (tincture). The following objectives were proposed to achieve this aim: qualitative screening of the antimicrobial activity of plant extracts, quantitative determination of the antimicrobial activity of plant extracts and in vitro investigation of the anti-biofilm properties of plant extracts. [16,17,18].

MATERIALS AND METHODS

Two plant extracts were analyzed in this study: Taraxacum officinale (dandelion) tincture and Chelidonium majus (tumbleweed) tincture.

Reference microorganisms were tested, two gram-negative bacterial strains: Escherichia coli ATCC 25922 and Pseudomonas aeruginosa ATCC 27853, two gram-positive strains: Staphylococcus aureus ATCC 25923 and Enterococcus faecalis ATCC 29212 and one fungal strain: Candida albicans ATCC 10231, according the American Type Culture Collection.

Qualitative evaluation of plant extracts was carried out by the drop method on solid agar medium by adapting the diffusimetric antibiogram method. Technique is: a 5µl volume of each plant extract was dropped onto the surface of a Plate Count Agar (PCA), non seleciv medium, inoculated with a standardized microbial suspension obtained from the strain to be tested by the cloth seeding technique. Sensitivity to a particular plant extract can be observed by inhibition of microbial growth around the deposited droplet. Interpretation of results: antimicrobial activity of the extracts was determined by assessing the formation of an inhibition zone around the deposited extract droplet and measuring its diameter using a millimeter ruler.

Quantitative determination of the antimicrobial activity of plant extracts was carried out by the microdilution method in liquid medium. Principle of the method: in 96-well ELISA microplates with liquid culture medium, 1/100 diluted microbial suspensions of the test strains are inoculated with an initial density of 0.5 McFarland in a gradient of plant extract concentrations. Minimum inhibitory concentration (MIC) and minimum bactericidal concentration (MBC) values are determined by drop seeding on agar medium the first 8 wells corresponding to 50%- 0.195% concentrations of each plant extract.

Interpretation of results: antimicrobial activity of the extracts was determined by evaluating the growth of microbial cultures on agar medium. The MIC value represents the concentration at which the plant extract inhibits the growth and multiplication of microorganisms, having a bacteriostatic effect, and the MBC value represents the concentration at which the plant extract has a lethal action on microorganisms, having a bactericidal effect.

Evaluation of the antibiofilm activity of plant extracts was tested by the 1% crystal violet microtitration method: following incubation of sterile 96-well ELISA microplates with liquid culture medium in which microbial suspensions are inoculated in a gradient of concentrations of the tested plant extracts, the in vitro antibiofilm activity of different concentrations of tinctures and alcoholic extracts is analyzed on the basis of absorbance values of the 1% crystal violet dye at 492 nm. Interpretation of the results: the antibiofilm activity of the plant extracts could be evaluated by determining the absorbance value from the spectrophotometric reading at 492 nm. The concentration of the plant extracts required to inhibit biofilm growth corresponds to the last well at which the absorbance value is less than half the absorbance value of the positive control corresponding to the same plant extract.

RESULTS

In this study we aimed to investigate the antimicrobial properties of some plant extracts of Taraxacum officinale (tincture) and Chelidonium majus (tincture). Qualitative evaluation of the antimicrobial activity of T. officinale plant extract determined an inhibition of microbial growth against E. faecalis ATCC 29212, P. aeruginosa ATCC 27853 and C. albicans ATCC 10231 strains, showing inhibition halo values of 9 mm, 8 mm with weak microbial growth within the microbial inhibition zone and 8 mm with the presence of a large number of colonies within the inhibition halo, respectively. Resistance to the action of the plant extract was recorded for strains of S. aureus ATCC 25923 and E. coli ATCC 25922, with the presence of T. officinale tincture not inhibiting their microbial growth.

Microbial growth of the fungal strain was inhibited in the presence of the plant extract from C. majus, resulting in an inhibition zone value of 7 mm. The same growth inhibition zone diameter was also recorded for the E.coli strain ATCC 25922, and a value of 11 mm was observed for the gram-positive strain E. faecalis ATCC 29212 (Table 1). This extract showed no antimicrobial activity against S. aureus ATCC 25923 and P. aeruginosa ATCC 27853 strains.

The qualitative determination study of the antimicrobial activity of S. marianum tincture on reference strains reveals that on both gram-negative strains, E. coli ATCC 25922 and P. aeruginosa ATCC 27853, and fungal strain, C. albicans ATCC 10231, the plant extract showed no antimicrobial activity (Table I). Inhibition of microbial growth could however be observed for the gram-positive strains S. aureus ATCC 25923 and E. faecalis ATCC 29212, with growth inhibition zone values of 9 mm and 8 mm respectively.

Table 1. - Quality determination of antimicrobial activity.

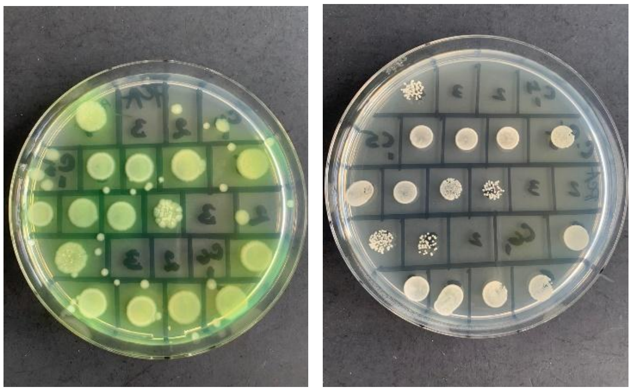
Strain tested	**Growth inhibition zone diameter (mm) and CMI**					
	T. officinale **(tincture)**	**CMI**	**Interpretation**	***C. majus*** **(tincture)**	**CMI**	**Interpretation**
S. aureus ATCC 25923	0	N/A	resistant	0	N/A	resistant
E. faecalis ATCC 29212	9^1	52µg/ µL	sensitive	1^1	4298 µg/ µL	intermediate
E. coli ATCC 25922	0	N/A	resistant	7^1	87 µg/ µL	sensitive
P. aeruginosa ATCC 27853	8^1	66µg/ µL	sensitive	0	N/A	resistant
C. albicans ATCC 10231	8^2	66µg/ µL	sensitive	7^1	87 µg/ µL	sensitive

Legend: [1]weak/slight microbial growth within the inhibition zone. [2]presence of a large number of colonies within the inhibition zone.

Formula: $CMI=Q/V$ $Q=10000\mu L$ $V=\pi R^2 G$ (1)

The method of quantitative determination of the antimicrobial activity allowed to highlight the concentrations of the plant extracts at which the growth and development of the tested reference strains are inhibited, as well as the concentrations determining the bactericidal action. (Fig. 1)

Figure_1 - Results of antimicrobial activity testing: Agarized, drop-seeded medium from 96-well microplates with strains of *S. aureus, E. faecalis, E. coli, P. aeruginosa* and *C. albicans* after incubation for 18-24h at 37ºC



The plant extract of T. officinale shows a strong inhibitory effect on gram-negative P. aeruginosa ATCC 27853 and fungal strains, the bacteriostatic effect being achieved at a concentration of 3.13%, while on gram-positive strains and E. coli ATCC 25922, the concentration of the plant extract required to inhibit microbial growth is 12.5-25%. On gram-negative strains and E. faecalis strain ATCC 29212, the 12.5% concentration of C. majus extract has a bacteriostatic effect, thus a medium inhibitory effect was recorded, but a weak and a strong inhibitory effect of this extract was observed on C. albicans ATCC 10231 and S. aureus ATCC 25923 strains, with MIC values of 50% and 3.13% respectively.

The tinctures tested in the study showed lethal action on the reference microbial strains at an average concentration of 20.8%. For the plant extract of T. officinale, a concentration of 12.5% was required for bactericidal effect on S. aureus ATCC 25923, E. coli ATCC 25922 and C. albicans ATCC 10231 strains, and for E. faecalis ATCC 29212 and P. aeruginosa ATCC 27853, concentrations of 50% and 6.25%, respectively, were required. In the presence of C. majus tincture, the lowest CMB value recorded was 6.25% for S. aureus strain ATCC 25923. Bactericidal action on E. faecalis ATCC 29212 and P. aeruginosa ATCC 27853 strains was observed at a concentration of 12.5% of the plant extract, while concentrations of 25% and 50% were required for the gram-positive E. coli ATCC 25922 and fungal strains, respectively.

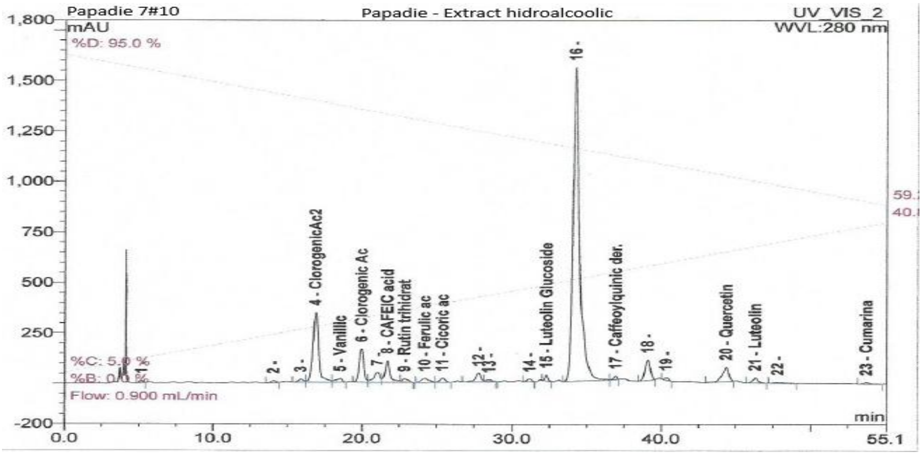
Analysis of spectrophotometric data revealed that T. officinale tincture shows little effect on Gram-positive strains, inhibiting biofilm growth at a concentration of 25%. The effect of this tincture was higher on gram-negative and fungal strains, with inhibition of biofilm growth observed at concentrations of 0.78%, 1.56% and 3.13% for C. albicans ATCC 10231, E. coli ATCC 25922 and P. aeruginosa ATCC 27853, respectively. The minimum concentration of C. majus tincture required to inhibit biofilm growth of C. albicans strain ATCC 10231 is 1.56%, while for E. faecalis ATCC 29212 and E. coli ATCC 25922 antibiofilm activity was achieved at a concentration of 12.5%, and for S. aureus ATCC 25923 and P. aeruginosa ATCC 27853 at 6.25%.

The chromatograms obtained in this study provide detailed information about the phytochemical composition of the extracts from Taraxacum officinale and Chelidonium majus. These analyses are essential for identifying the active compounds involved in the observed antimicrobial activity and for correlating them with the experimental results.

The attached figures present representative chromatograms for each extract, highlighting the main absorption peaks and specific compounds. This information contributes to a better understanding of the mechanisms through which the substances in the studied plants act against various microbial strains. The presence of active compounds is clearly demonstrated, supporting the qualitative and quantitative results obtained in the antimicrobial activity tests.

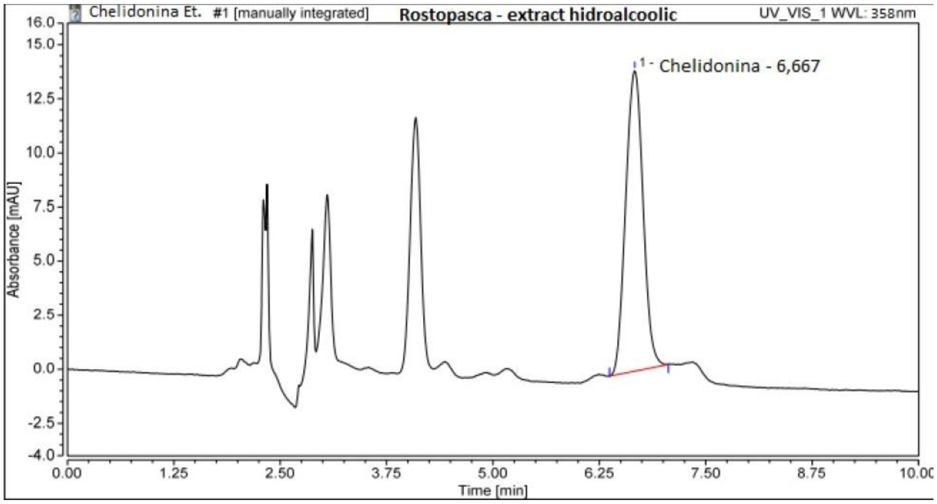
The chromatogram represents the analysis of hydroalcoholic extract of Taraxacum officinale, (Fig. 2) highlighting major phytochemical compounds such as luteolin glucoside (the main peak, indicating the dominant compound), caffeoyl derivatives, and luteolin. Additionally, chlorogenic acid and quercetin are present, known for their antioxidant and anti-inflammatory activities. This composition suggests a high therapeutic potential, supporting the antimicrobial activity observed in the study.

Figure_2 Chromatogram of hydroalcoholic extract of *Taraxacum officinalis*



The chromatogram analyzes a hydroalcoholic extract of Chelidonium majus (Fig. 3), highlighting chelidonine as the main compound (retention time 6.667 minutes), suggesting a high concentration. Chelidonine is an alkaloid known for its antimicrobial and antitumor properties. The smaller peaks indicate the presence of other alkaloids, such as sanguinarine or berberine.

Figure 3_ Chromatogram of hydroalcoholic extract of *Chelidonium majus*



DISCUSSION

The present study investigated the antimicrobial properties of plant extracts tinctures from Taraxacum officinale and Chelidonium majus. The qualitative and quantitative evaluations of antimicrobial activity revealed differential effects of these plant extracts on different strains, shedding light on their potential therapeutic applications.

Taraxacum officinale L. is a flowering herbaceous perennial plant of the Asteraceae family. Interest in researching the biochemical characteristics as well as the pharmacological properties of this species increased considerably in the 1950s, and numerous active substances have now been identified, including flavonoid compounds, phenolic acids such as cyclonic, chlorogenic and caffeic acid, alkaloids, and terpenes. In modern medicine, this plant is marketed and used as an herbal treatment to relieve symptoms of conditions such as arthritis, hepatic disorders and to suppress oxidative stress [17,18, 19,20,21,22,23]. Dandelion exhibits a diverse array of pharmacological effects, making it a valuable medicinal plant with potential therapeutic applications. The study by Trinh et al. 2020, reported that ethanol-based plant extract from T. officinale exhibits bactericidal effect on S. aureus strain ATCC 25923 at a concentration of 20 mg/ml [24]. T. officinale extract tested in the study by Sangeetha and Ezhilarasan 2016, showed lethal action on E. faecalis strain ATCC 29212 at a concentration of 200mg/mL [25]. The study by Shah et al. (2011) [26] showed that S. marianum extracts did not exhibit antimicrobial activity against the tested gram-negative strains E. coli ATCC 25922 and P. aeruginosa ATCC 27853.

Chelidonium majus is a medicinal plant belonging to the Papaveraceae family that is found in the wild flora of Europe, Asia, North America, as well as in some regions of Africa. It is widely used in traditional herbal medicine to treat conditions including biliary and hepatic dysfunction, jaundice and to relieve pain caused by edema. It has antidiuretic, spasmolytic, sedative, and antimicrobial properties. The dried aerial part of C. majus is an official medicine in the pharmacology of European countries, but it is necessary to administer it under the supervision of authorized medical personnel due to the presence of a rich concentration of isoquinoline alkaloids. [27,28,29,30,31]

The antimicrobial activity of the studied plant extracts varied significantly depending on the microbial strain and the type of extract used. For instance, T. officinale exhibited inhibition against E. faecalis and P. aeruginosa strains but not against S. aureus and E. coli. Similarly, C. majus showed inhibition against E. faecalis and C. albicans but not against S. aureus and P. aeruginosa. These findings suggest that the efficacy of plant extracts may be strain-specific, highlighting the importance of considering multiple strains in antimicrobial studies. [32,33,34,35]

The results of this study are consistent with some previous findings but differ from others. For example, the antimicrobial activity of T. officinale against S. aureus strain ATCC 25923 reported by Trinh et al. (2020) aligns with our findings, whereas Tunç et al. (2019) reported no antimicrobial activity against E. faecalis strain ATCC 29212, contradicting our observations. Such discrepancies may arise from variations in extraction methods, microbial strains, or growth conditions, emphasizing the need for standardized protocols and comprehensive strain selection in antimicrobial research.

The determination of MIC and bactericidal concentration provided insight into the potency of the plant extracts against different microbial strains. Higher MIC values were often observed for gram-negative bacteria compared to gram-positive bacteria and fungi. This differential susceptibility underscores the complex interplay between microbial cell wall structures and the mechanisms of action of plant compounds.

The ability of plant extracts to inhibit biofilm formation is of particular interest due to the role of biofilms in antimicrobial resistance. Our study demonstrated varying degrees of biofilm inhibition by the tested extracts, with some showing promising activity against both gram-positive and gram-negative bacteria as well as fungi. These findings suggest the potential of plant extracts as adjuncts in combating biofilm-associated infections.

Despite the valuable insights provided by this study, several limitations should be acknowledged. The use of reference strains may not fully represent the diversity of clinical isolates, warranting further investigations with clinically relevant strains. Moreover, elucidating the underlying mechanisms of antimicrobial activity and conducting in vivo studies are crucial steps toward clinical translation.

The chromatographic analysis of the hydroalcoholic extracts of Taraxacum officinale and Chelidonium majus revealed the presence of major bioactive compounds, each contributing to the specific therapeutic potential of the plant. The chromatogram of Taraxacum officinale indicated Luteolin glucoside as the main compound, known for its antioxidant and anti-inflammatory activities, alongside caffeoyl derivatives. For Chelidonium majus, chelidonine (retention time 6.667 minutes) was identified as the major compound, recognized for its antimicrobial and antitumor properties.

These results emphasize that each extract possesses a distinct phytochemical composition that may synergistically contribute to the observed antimicrobial activity. The identification of specific compounds through chromatographic analysis supports the understanding of the mechanisms of action of the extracts and justifies further investigations into their use in antimicrobial, antioxidant, and hepatoprotective treatments. This study underscores the diverse antimicrobial potential of plant extracts against a range of microbial pathogens. Further research focusing on standardization, mechanism of action, and clinical efficacy is warranted to harness the therapeutic benefits of these natural products effectively.

CONCLUSION

In this experimental work, the antimicrobial properties of two plant extracts of Taraxacum officinale (tincture) and Chelidonium majus (tincture) were studied on 5 reference bacterial strains, two gram-positive (Staphylococcus aureus ATCC 25923 and Enterococcus faecalis ATCC 29212), two gram-negative (Escherichia coli ATCC 25922 and Pseudomonas aeruginosa ATCC 27853) and one fungal strain, Candida albicans ATCC 10231.

Qualitative testing of antimicrobial activity revealed that the plant extracts inhibited the growth and development of the tested microbial strains.

Quantitative determinations of antimicrobial activity allowed the determination of the concentrations of plant extracts responsible for the bacteriostatic and bactericidal effect, and a higher sensitivity of microbial strains could be observed in the presence of tinctures.

In vitro evaluation of the antibiofilm activity of plant products revealed their ability to inhibit the development of biofilms on inert substrate; plant extracts of C. majus were found to inhibit biofilm formation in all bacterial strains tested, while tincture of T. officinale showed very good activity on gram-negative and fungal strains.

The results obtained are promising, supporting further research into the biochemical characteristics of these extracts in order to formulate strategies for the control of bacterial and fungal infections in humans.

Abstract: With the increase of the medium lifespan in developing countries, skin aging rise attention more and more. In 2007, Kaya and Saurat rebranded the extreme expression of skin fragility under the name of ‘‘dermatoporosis’’ or chronic cutaneous insufficiency/fragility syndrome. Dermatoporosis is still underused in medical literature and nurses and wound specialists know also about this condition, but they call it "skin tears". There is obvious confusion cause the nursing literature talks about skin tears while dermatologists write about dermatoporosis. Clinical aspects comprise atrophy, purpura, and pseudo-stellate scars. Firstly, the British dermatologist Thomas Bateman described senile purpura in 1818 as purpuric patches arising in elderly people after minimal trauma, especially on the dorsum of the hands. Furthermore, between 1970 and the full documentation of Kaya and Saurat in 2007, we found medical papers about senile purpura, pseudoscars, skin tears, and so on. Starting from this historical data, they bring valuable information according to clinical aspects, histopathology, ultrasonographic aspects, pathophysiology, and therapeutics. This paper aims to analyze published data for improving the diagnosis and management of dermatoporosis.

Keywords: dermatoporosis

HISTORY

With the increase of the medium lifespan in developing countries, a new type of dermatosis was described in 2007 by Kaya and Saurat under the name of ‘dermatoporosis’ of chronic cutaneous insufficiency/fragility syndrome [1,2,3]. Clinical aspects comprise atrophy, purpura, and pseudo-stellate scars (Figure 1). Firstly, the British dermatologist Thomas Bateman described senile purpura in 1818 as purpuric patches arising in elderly people after minimal trauma, especially on the dorsum of the hands [4]. Later, in 1967 Colomb reported pseudo-stellate scars as fibrous scars with a stellate aspect arising on the forearms of the elderly [5]. One year after this description, Frederik and Zak made the connection between stellate pseudoscars and senile purpura, describing that both arise on the forearms of the elderly after minimal traumas. They also report that the shape of these scars can be round or linear, not only stellate [6]. In 1972, Colomb described the trade consisting of atrophy, Bateman's purpura, and spontaneous pseudo-scars The term pseudoscars seems to be related to the fact that there is no solution of continuity with the exterior, the lesions are produced by a compression trauma without true lesions in the extreme external part of the skin, the epidermis [5,7]. Furthermore, there is a lack of reports between 1970 and the full documentation of Kaya and Saurat in 2007. Starting from this historical data and personal clinical cases, they bring valuable information according to clinical aspects, histopathology, ultrasonographic aspects, pathophysiology, and therapeutics [3]. The prevalence of dermatoporosis is about 30% in patients older than 65 years, but this aspect can vary according to the recruitment group: non-hospitalized patients, inpatients, outdoor patients, and patients for rehabilitation centers. The aim of this paper is to analyze published existing data for improving the diagnosis and management of dermatoporosis.

RISK FACTORS AND COMORBIDITIES

Only the future will decide if dermatoporosis is the expression of the general process of senescence, chronic sun exposure or even both [3]. Firstly, some data indicate that patients could have a genetic predisposition according to the connection with atopic dermatitis [8]. Furthermore, analyzing some aspects of aquaporines and skin aging previous statement is increased [9]. Aging plays a major role, the aging process acts mainly through chronic sun exposure, especially the professional type [3].

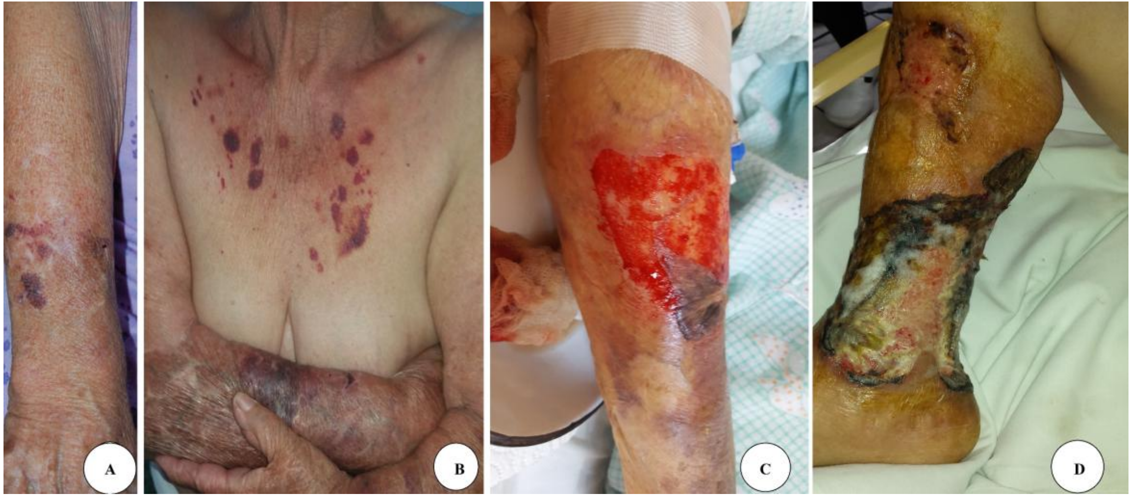

Figure 2: Bleeding after repeated procedures for peripheral vein catheterization in a female patient with primary dermatoporosis

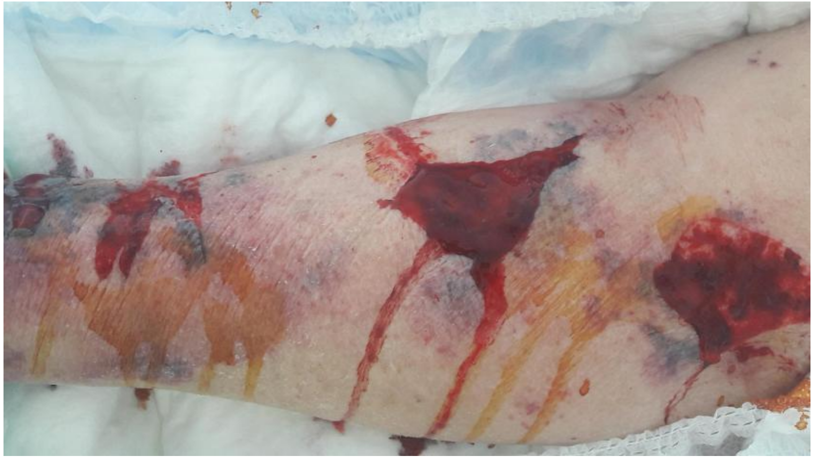

Intrinsic aging or endocrine aging plays a role, the disease is more frequent in postmenopausal women [10]. On the other way, seems that maternal age > 40 years at last pregnancy, breastfeeding for > 7 months per pregnancy and > 18 cumulative months, age < 20 years at first pregnancy, and menopause after 45 years play a protective role against dermatoporosis [11]. Iatrogenic factors like systemic steroid usage especially in patients with blistering diseases can induce dermatoporosis by decreasing the extracellular matrix leading to skin atrophy.

Regarding topical steroids seems that only clobetasol propionate 0.5% can induce dermatoporosis, can it be used for more than six months, this aspect can be visible on the forearms in patients with psoriasis (Figure 3) [12]. The author documented also an interesting case of a 42 female old patient suffering from a secreting cortisol tumor with a Cushing syndrome aspect and typical lesions of dermatoporosis on the forearms (Figure 4). Other medications could be anticoagulants, and epidermal growth factor inhibitors (EGFR) used in the treatment of different carcinomas (Figure 5). Associated comorbidities like osteoporosis, renal failure, and anemia were cited [13].

Moreover, there is a strong connection between the degree of osteoporosis and dermatoporosis [14,15]. It is not clear yet if osteoporosis has a direct influence on the onset of dermatoporosis or if both are the result of the general aging process having hormonal disturbances at the base. Additional information was brought by Kluger in 2016 describing the possible connection of dermatoporosis with the lack of vitamin C levels [16]. Laboratory data about skin expression or serum levels of vitamin C and dermatoporosis are lacking. This correlation is based only on the benefits of topical or systemic administration of vitamin C [16,17].

Recently, vitamin D deficiency was also proposed as a factor by Romano et al based on the connection between osteoporosis and dermatoporosis. Anyway, correlation data between decreased levels of vitamin D and dermatoporosis degree in the elderly are necessary for validation [18]. Finally, most of the patients present an association of these risk factors.

Figure 3: Secondary dermatoporosis: A) Secondary dermatoporosis in a female patient treated with 0.5 mg prednisone per kilo of body weight for 4 months for bullous pemphigoid; B, C) Secondary dermatoporosis in 2 patients treated with 1 mg per kilo of body weight prednisone for 5 months for pemphigus vulgaris.

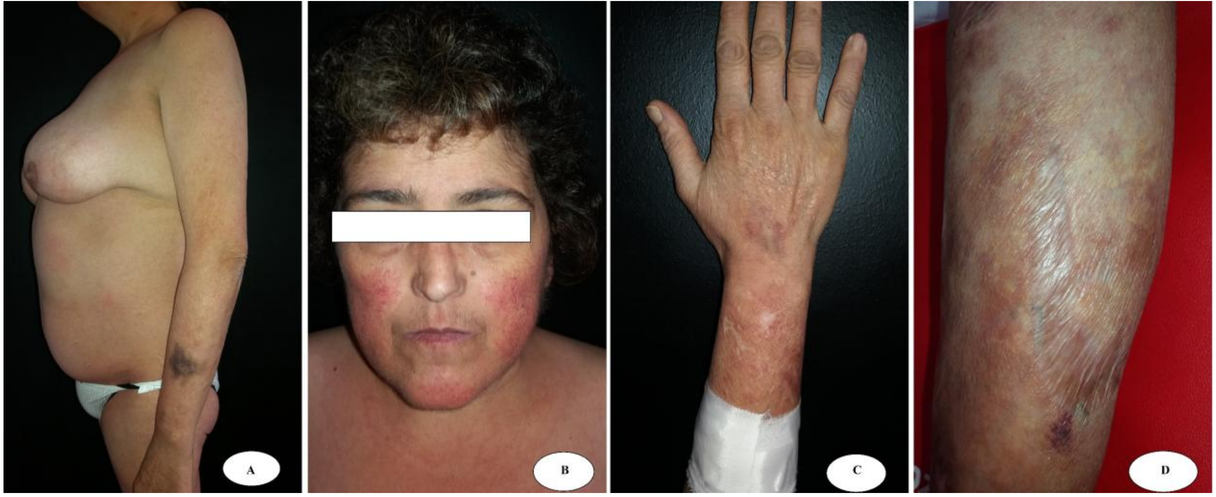

Figure 5: Dermatoporosis in patients undergoing erlotinib in a 67- year-old female patient undergoing erlotinib for lung cancer.

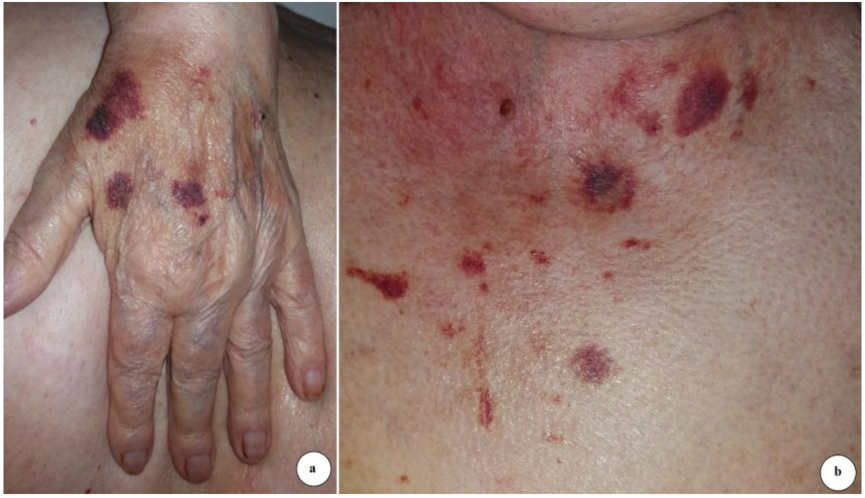
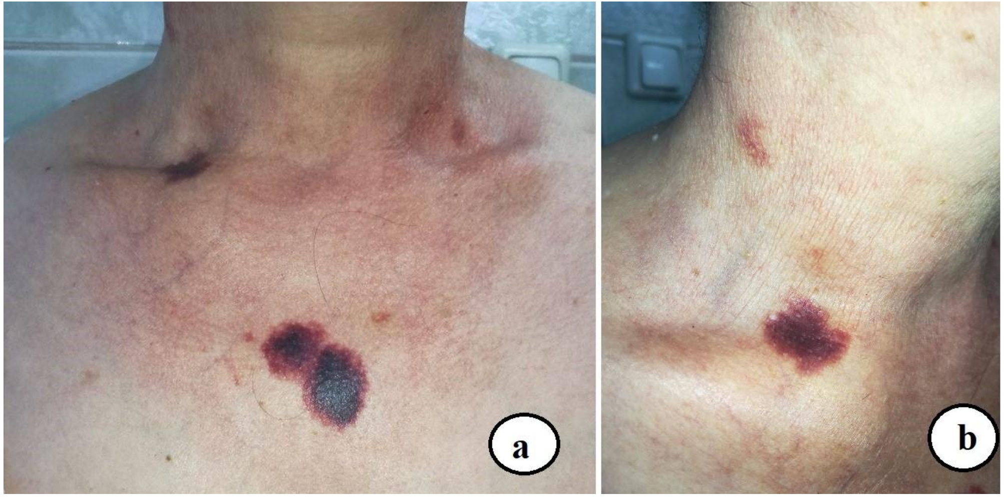


CLINICAL ASPECTS

The clinical changes are skin atrophy, purpura, pseudoscars, hyperpigmentation, and ulcerations. Due to atrophy, there is an increased risk of the appearance of superficial or dissecting hematomas of the skin that form by the accumulation of blood in between the hypodermis and the muscular fascia due to local traumas [3,19]. Most lesions are located at the level of the forearms and shins [3]. Other sites are the chest, arms, and dorsal parts of the hands. It is a tendency for females to develop lesions on the chest and face compared with men. The appearance of lesions at the level of the face and scalp is reported in rare and isolated cases [3,10]. Skin atrophy is the main sign of dermatoporosis. It is essential for the development of the other changes, so that, on the background of exposure to trauma of the underlying structures, purpura and skin ulcers develop. These heal with hyperpigmentation and scars [3]. Senile purpura (Thomas Bateman, 1818) occurs in the elderly, especially on the backs of the hands, and is often found in the context of dermatoporosis [3.4]. It has a complex mechanism, being produced by both exposure of blood vessels due to atrophic skin, and by a decrease in the elastic fibers of the vascular endothelium. An increase in capillary permeability with age is also taken into account [4,20]. Colomb stellate pseudoscars are found on the forearms of the elderly and are produced by defective remodeling of the extracellular matrix due to functional disturbances of enzymes such as metalloproteinases [21]. Appearance on the shins and other sites is also possible. They can be stellate, linear, or plaque-like. The stellate ones are the most common [3,10]. They are formed by the rupture of collagen fibers but without clinical evidence of a break in continuity at the level of the epidermis. Repair is done by excessive proliferation of fibrous tissue, which leads to a clinically hypertrophic scar appearance [5,7]. Pseudoscars are found in approximately 30% of people over the age of 70. Hyperpigmentations appear as residual lesions and as a sign of photodamaged skin [3,10,21]. Cutaneous ulcerations appear based on the cutaneous atrophy after some unnoticeable frequent minimal traumas. They appear at the level of the extremities [3].

Figure 6: Dermatoporosis in a 52-year-old-female patient undergoing erlotinib for breast cancer



NATURAL COURSE AND COMPLICATIONS

When the cause is obvious like usage of corticosteroids, local or oral, disruption of the treatment can improve greatly and stop the development of further purpura. Superficial hematomas are due to blood accumulation between the dermis and the subcutaneous fat. Clinically appears as a detachment of a skin region from the subjacent adipose tissue. They appear in the advanced stages of dermatoporosis and are found at the level of the shins as well as at the dorsal surface of the forearms [3]. Deep Dissecting hematomas of the skin (DDH) represents the main complication of dermatoporosis. They form as the accumulation of blood between subcutaneous fat and muscular fascia. It represents a surgical emergency due to the risk of block detachment of the cutaneous structures with exposure to infections of major muscular tissue areas. Due to the profound localization of blood collection, the detachment of the skin does not occur immediately. Thus, the lesions mimic cellulitis, presenting as painful erythematous-edematous plaques. People over 80 years with are affected, especially the females and they are located strictly on the calves. The positive diagnosis is done through magnetic resonance imaging (MRI) that shows a hypoechogenic band in the virtual space located between the hypodermis and the muscular fascia. DHH represents a major complication of the disease, the emergency surgical drainage being necessary. The repair of the residual defects is done slowly by the application of topical hyaluronic acid or with skin grafting [3,19] The development of non-melanocytic skin cancer is possible also on dermatoporotic skin, the author saw a case of actinic keratosis and one of cutaneous horn arising in the area of dermatoporosis (Figure 6).

DIAGNOSIS

Clinical aspects are usually enough for the diagnosis. More than that, Saurat developed a self-diagnosis tool (IDA: Index Dermatoporosis Assessment) consisting of a two-module questionnaire that is addressed to individuals aged ≥65 years. The technique was validated in France and Mexico. Skin ultrasonography quantifies the grade of atrophy showing a thickness of skin approx. 0.7-0.8 mm at the level of the regions with dermatoporosis (normal value = 1.3-1.5 mm). The usefulness of reflectance confocal microscopy

(RCM) for the diagnosis of dermatoporosis and quantifying skin thickness was proven by Mezinger, but is expensive and not accessible for routine. Electronic microscopy highlights the disorganization of collagen with parallel exposure of the fibers on the surface of the epidermis (88). Anyway, skin biopsy is an invasive tool, so is recommended to be avoided in such patients and usually is unnecessary when the diagnosis is obvious but might be necessary to rule out other diagnoses in case of atypical location or isolated lesions. For these cases, a 3 mm punch biopsy can be performed on non-erosive/ulcerated lesions without any risk. A general blood count to exclude bleeding disorders, exploration of renal function, and osteoporosis assessment is strongly recommended [3,8]. The fragility of dermatoporotic areas with bleeding and delayed healing results in significantly limited skin biopsies and secondary histopathological and immunohistochemistry studies.

CLASSIFICATION AND STAGING

Depending on the main etiological factors, dermatoporosis can be classified as primary or secondary. Regardless of the form, the lesions are located on the same regions of election such as forearms, shins, anterior part of the thorax, and dorsum of hands [3,10]. Face and scalp location was also cited [10]. Primary dermatoporosis or actinic is due to chronic exposure to the sun, especially in patients over 60 years who are affected. Secondary dermatoporosis lies behind iatrogenic factors, especially the prolonged utilization of corticotherapy. It is characterized by the possibility of the lesions appearing under the age of 60 as well as by partial or complete resolution of the lesions after corticotherapy cessation [3]. The systemic usage as well as topic one can lead to the development of the lesions. Regardless of the way of administration or the cutaneous location in the case of local therapy, the lesions develop in s the same regions/ zones as well as in primary dermatoporosis [3,6]. The disease presents four evolutionary stages. The first stage is characterized by atrophies, purpura as well as pseudo scars, and adding the presence of cutaneous ulcerations leads to the second stage. In the third stage, the ulcerations are increased in size and number. Development of DDH is characteristic of the fourth stage [3,6,19].

PREVENTION AND TREATMENT

The prevention consists firstly in avoidance of the triggers. Regarding this, there is the necessity to use the factors for photoprotection and the avoidance of trauma in patients who are already suffering from primary dermatoporosis. Careful organization at home with the furniture (« coffee table syndrome »), prevention of falling, also proper information of nursing staff the way they handle the patients, no adhesive directly on the skin, avoid excessive application of potent or highly potent corticosteroids. The first topical was proposed by Kaya in 2007, at the same time as the disease was described. The application of hyaluronic acid 1% leads to the improvement of the lesions [3]. In a recent study, topical or oral hydrolyzed collagen does not improve precocious lesions of dermatoporosis – stage I [23]. Topical retinoids are cited to be efficient in the treatment of dermatoporosis since their role is the re-establishment of the differential cellular process. The use of the combination of hyaluronic acid and retinyl-aldehyde is more effective than the separate application of these two [24]. Alpha-hydroxy-acids (AHA) are efficient by diminishing the grade of atrophy [25]. Humbert and colleagues sustain that dermatopororis, especially the Bateman senile purpura, is due to a deficit of vitamin C skin level and it shows an abatement of the lesions after applying topically vitamin C 5% [17]. There is limited data regarding the efficacy of topical application of topical human epidermal growth factor or dehydroepiandrosterone [26,27]. Systemic administration of vitamins C and D could bring some benefits [16,18]. An isolated case of dermatoporosis in the upper limbs treated with polymethylmethacrylate (PMMA) using the BioSculpt®technique was reported.

Methods of assessing stable coronary artery disease by non-invasive imaging techniques

Carmen M. Voicu[1], **Tiberiu Nanea**[2]

Abstract: *Diagnosis of stable coronary artery disease is vital for prognosis, classification and early treatment. Current guidelines show that patients with stable angina who are suspected of CAD need to undergo a certain protocol for classification and further analysis. This review's aim is to present the most used non-invasive techniques for identification of CAD and to underline the current development of imaging technology and the possible reduction of invasive measures due to non-invasive techniques.*

Currently, non-invasive techniques used to diagnose stable coronary artery disease have a very high accuracy and newer methods seem to be comparable to the gold-standard. The majority of the methods discussed have an optimal performance for patients with PTP between 15-85%, and the future of diagnosis for these patients seem to involve less invasive measures and less radiation by improving the current devices and by usage of machine-learning algorithms.

Keywords: *coronary artery disease, PTP, stress echocardiography, SPECT, CMR, CCT*

INTRODUCTION

Diagnosis of stable coronary artery disease is vital for prognosis, classification and early treatment. Failure in doing so, might determine secondary events such as: disease progress, myocardial infarction or even death.

Current guidelines show that patients with stable angina who are suspected of CAD need to undergo a certain protocol for classification and further analysis.

This review's aim is to present the most used non-invasive techniques for identification of CAD and to underline the current development of imaging technology and the possible reduction of invasive measures due to non-invasive techniques.

METHODS

A PubMed review was performed, analyzing all publications from 1968 to 2019 concerning the topic "stable coronary artery disease" (keywords: coronary artery disease, PTP, stress echocardiography, SPECT, CMR, CCT). Human studies and meta-analyses, published in English, were cited in this review.

RESULTS AND DISCUSSION

Diagnosis and management

According to current guidelines, patients with suspected SCAD will follow a step-by-step approach for confirmation.

After the clinical examination and basic tests applied (ECG, bio-chemistry indicators, resting echocardiography), if the cause of chest pain is none other than CAD and the left ventricle ejection fraction is higher than 50%, the evaluation of suspected SCAD commences (patients with LVEF<50% have a high risk for cardiovascular events and they should have ICA without further testing). [1]

First step is to determine the pre-test probability of SCAD

[1] Clinical Emergency Hospital Bucharest, Romania
[2] Prof. Dr. Th. Burghele" Hospital, Bucharest, Romania

(PTP). This indicator is evaluated by the age, gender and the nature of symptoms for the suspected patient, and evaluates the probability of having a coronary artery disease before realizing any tests.

Non-invasive imaging techniques that assess coronary artery disease usually have sensitivities and specificities around the value of 85% (coronary computed tomography angiography – coronary CTA has the highest sensitivity (95%) [2] while stress echocardiography has the highest specificity (94.6%) [3]). This is why for 15% of the patients, most imaging techniques will be false positive and therefore, for these patients (with PTP < 15%) performing no non-invasive imaging tests will bring less incorrect results. Therefore:

- patients with PTP < 15% will not do any further investigations;
- patients with PTP between 15-65% are recommended to have an exercise ECG as the initial test and afterwards if necessary, perform imaging tests;
- patients with PTP between 66-85% must have a non-invasive imaging test for confirmation;
- patients with PTP over 85% are assumed to have SCAD, so they don't need further investigations. [1]

As such, patients with PTP between 15%-85% are required to be assessed with non-invasive techniques for risk stratification and selection for invasive measures (revascularization or ICA). [4]

Electrocardiogram exercise testing

As described above, for patients with PTP within 15-65% for suspected SCAD, an exercise electrocardiogram will be the first and best option.

According to the Bruce protocol, this test involves using a treadmill or an exercise bicycle in which patients are monitored using a continuous 12-lead ECG and their blood pressure measured, when they are exercising. The level of difficulty increases incrementally every 3-minutes until a certain target is reached (the predicted heart rate for the age of the patient) or the patient cannot continue the test. [5]

If ST-depression is present with a value of ≥ 0.1mV or 1 mm, in one or more ECG leads, which persist at least 0.06-0.08 seconds after the J-point, the test detects a possible CAD. [1]

Data shows that the usefulness of the test might come for its higher specificity, one study shows a sensitivity of 45%, and specificity of 85% [6] while another study shows higher values for men (sensitivity – 40%, specificity – 96%) than for women (sensitivity – 33%, specificity – 89%). [7]

Also, in a meta-analysis which compared the efficacy of exercise stress testing between 34 studies, results also showed that for men a positive exercise test results in a 89% probability of CAD, and for women results in a 69% probability of CAD. Whereas, a negative exercise test leads for men to a 37% probability of CAD and for women to an 18%. These values show that a large share of patients may be undetected after performing an exercise stress test. [8]

This method is useful only for patients that don't have ECG abnormalities at baseline. For example, patients with Wolff-Parkinson-White syndrome, paced ventricular rhythm, LBBB, use of digitalis, atrial fibrillation, left ventricular hypertrophy with repolarization changes or digoxin use, have a higher likelihood that the observed ST-segment depressions would happen because of the baseline pathology and not the CAD. Therefore, in these patients the ECG results aren't interpretable and exercise ECG testing should not be performed. [9]

Despite all the results, for low-risk patients, for example women, the standard ECG exercise treadmill test should be the first diagnostic strategy, because of its availability and lower costs of usage. Additional imaging techniques, like myocardial perfusion imaging (MPI) does not add any substantial benefit to the exercise treadmill test, but increases diagnostic costs significantly [10].

Also, it is safe to say that during exercise testing, the risk of having myocardial infarction because of the increase in the pro-coagulant activity, doesn't increase for patients with CAD (objectified angiographically) in comparison to those who don't have CAD, meaning that the method is in general safe. [11]

Although this method is accessible for diagnosis of CAD, in the near future it will probably be replaced with other more accessible, non-invasive imaging techniques. Cardio-goniometry (3D-ECG) was demonstrated to have a higher performance in diagnosis (sensitivity 75% vs sensitivity 68.1% - exercise ECG and specificity 74.4% vs specificity 38.1% - exercise ECG) of CAD in women, and being able to have this efficacy without having to undergo stress-testing and being practically free-of-risk, surely proves an improvement in easiness and performance in the diagnosis of CAD for the near future. [12]

Stress echocardiography

Another imaging technique for the assessment of stable CAD is stress echocardiography. This method usually involves a mechanical stressor (exercise performed on a treadmill or a bicycle) or a pharmacological agent.

The principle of stress echocardiography is the identification of functionality for all cardiac walls and further classification into normal, ischaemic, viable or necrotic myocardium:

- normal myocardium responds with normokinetic function at rest and during stress it may have a normokinetic or hyperkinetic function;
- ischaemic myocardium may have a normal function at rest, but during stress its response worsens, having a hypokinetic/akinetic/dyskinetic function;
- viable myocardium testing in dysfunctional myocardium at rest shows a improvement during stress response because it would indicate a region of hibernating myocardium that improves its function after revascularization;
- necrotic myocardium doesn't improve its function during stress, a region of dysfunctional myocardium at rest has its function fixed. [13]

Stress echocardiography using exercise stress is preferable because it provides additional data like exercise time, workload, heart rate and blood pressure variability. Pharmacological stress using dobutamine can be used for patients who are unable to exercise. [1]

Also using dobutamine bring the advantage of assessment of viability more accurately than exercise stress echocardiography. Ischaemic but viable myocardium at low doses of dobutamine (10-20 μg/kg/min) improves its function, but at high doses (40 μg/kg/min) its function worsens. This effect is due to the initial inotropic function of dobutamine at low doses, whereas in high doses its function changes to chronotropic and especially vasodilatory. [14]

Using additional contrast to the method (by using microbubbles of encapsulated gas) can bring enhancement of the images viewed, by improving image quality, accuracy of detection of CAD and reader confidence, especially when certain segments cannot be visualized at rest. [15]. Newer data show data coronary microvascular dysfunction (a potential cause for chest pain) can be observed using myocardial contrast echocardiography, a marker for possible CAD, patients with this issue having lower hyperemic perfusion and microvascular flux rate than patients with normal microvascular function. [16]

Diagnosis of CAD using stress echocardiography is quite efficient. Exercise stress echo, dobutamine and dipyridamole stress echo show sensitivities of 85%/80%/78% and specificities of 77%/86%/91% for detection of CAD, which are significantly better than electrocardiogram exercise testing, and similar to SPECT [17]

Also, using strain-rate imaging and tissue Dopple imaging can improve the quality of detection for CAD. Because the interpretation of images in most echocardiographies are subjective and prone to errors, measuring strain-rate can determine an objective view on the diagnosis. Voigt et al showed that ischemic segments had significantly higher peak systolic strain-rates and strains during ejection time during dobutamine stress than nonischemic segments [18] and Gupta et al., recently showed in a meta-analysis similar results, analysis of longitudinal strain imaging having higher AUC-ROC prediction of CAD (0.92) than assessment of wall motion (0.83). [19]

The newest advancement in echocardiography for detecting CAD markers is the 3D-speckle tracking echocardiography (3D-STE). One of the most used scoring systems to objectify CAD severity is the Gensini score. In one study, using 3D-STE to measure 4 parameters of CAD (global longitudinal strain – GLS, global circumferential strain – GCS, global radial strain – GRS and global area strain – GAS) it had been found that patients found with critical CAD after coronary angiography had significantly worse values of GLS,GCS,GRS,GAS than patients with noncritical CAD. Also the Gensini score had a significant positive linear correlation with GLS and GAD, meaning that 3D-STE was a very good method do identify the grade of severity of CAD. [20]

SPECT (Single photon emission computed tomography) – Myocardial perfusion scintigraphy

One of the most used imaging techniques, uses similar principles like the previously described methods. It uses either exercise stress or pharmacological stress (e.g. adenosine, dipyridamole, dobutamine, regadenoson) and measures the level of uptake of radioactive tracers at rest level and stress level from the myocardium. In ischemic tissue, due to the lower blood flow in stress response, the uptake of the tracer is reduced, meaning a positive test for diagnosis of CAD. [4]

Standard radiotracers are Technetium-99m (^{99m}Tc) or Thallium 201 (^{201}Tl), although the latter has a higher radiation dose. New developments in this technology (cadmium-zinc-telluride – CZT) show a significantly higher performance than conventional SPECT and a lower dose of radiation. [21] Also another radiotracer (for PET) that is frequently used is Rubidium 82 (^{82}Rb) that is associated with lower radiation exposure and high sensitivity (82%) and specificity (90%) for detecting ischaemia. [22]

The method also compares ischaemic areas of myocardium to normal areas. Some patients (with triple vessel disease) whom hearts have a widespread ischemia, will be detected false-negative for CAD because of the lack of inducing ischemia in the underperfused myocardium, proving a limitation of the method. [23]

Another limitation of the method would be diagnosis of CAD in patients with left bundle branch block (LBBB). In those patients, the intraventricular septum has a delay in contraction (being dyskinetic), and in the moment of image acquisition may have a lower thickness, indicating a LAD territory ischaemia, and thus a false-positive result. [24]

Also, for asthmatic patients that are undergoing SPECT, using adenosine is a contraindication because of the possible precipitation of bronchospasm due to activation of all adenosine receptors (especially A_1, A_{2B} and A_3). Regadenoson, a selective A_{2A} agonist (for producing hyperaemia) is currently used for these patients, because of its sufficient hyperaemic response, less side effects, and comparable efficacy to adenosine. [25]

The REASSESS study, in which in a prospective manner was assessed the diagnostic performance of coronary computed tomography angiography (CTA) vs. SPECT, showed that although many cases of stable CAD wouldn't have been diagnosed by SPECT if invasive measures (angiography) wouldn't have been taken, the overall performance of both of the methods (CTA and SPECT) was similar, in objectifying hemodynamically significant stenosis, having a similar accuracy (70% - CTA vs. 68% SPECT). [26]

The issue of false-negative results in SPECT, although present, is indicated to have a low prevalence and thus, a low impact. For example, in 133 patients with normal SPECT results, only 16% had anatomically and functionally significant stenoses, and from 180 vessels analyzed with normal SPECT results, only 8.33% had stenoses. As such, the prevalence of false-negative cases in normal SPECT remains low and a normal result stays important in diagnosis and follow-up. [27]

SPECT also predicts efficiently long-term outcomes. Patients with ischaemia burden, who had SPECT and also underwent early coronary revascularization had significantly lower all-cause mortality and cardiac mortality in comparison to patients who received only pharmacological therapy, indicating a significant diagnostic value for the severity of CAD by using SPECT. [28]

Usage of myocardial perfusion scintigraphy combined with positron emission tomography is more accurate in comparison to SPECT, having higher sensitivities (90% - PET, 85% - SPECT) and higher specificities (88% - PET, 85% - SPECT), also AUC-ROC prediction was higher for PET (0.95) in comparison to SPECT (0.90), according to Mc Ardle et al. [29]

A similar study showed better image quality and diagnostic accuracy of CAD for PET in comparison to SPECT (showing a percentage of 78%/79% excellent image quality of rest/stress PET scans vs. 62%/62% excellent image quality of rest/stress SPECT scans). [30]

Data also shows that using PET-MPI to determine myocardial blood flow is excellent and superior to the relative measurement of tracer uptake, being more efficient for the detection of CAD and eliminating false-negative patients with balanced ischaemia (triple vessel disease). [31]

New technology in PET-MPI for diagnosis of CAD show similar results as described above, for usage of flurpiridaz ^{18}F in comparison to SPECT, bringing more advantages for PET-MPI (higher quality images, diagnostic certainty of interpretation, and sensibility of detection of CAD). [32]

Cardiac magnetic resonance

One of the most advantageous methods of imaging techniques, because of the high-detail images, non-invasivity and lack of any ionizing radiation, cardiac magnetic resonance can identify CAD, even better than the previous methods discussed. Similar to all CAD detection methods, is uses a stress agent, exercise or pharmacological.

Stress cardiac magnetic resonance using both a bicycle [33] and a treadmill [34] seems feasible for detection of CAD. Recently, the EXACT study, which used stress CMR with a treadmill, showed a sensitivity of 79% and a specificity of 99% for detection of CAD after using a SPECT, also showed higher agreement of diagnosis with angiography (k=0.82) than SPECT (k=0.46), demonstrating as such excellent diagnostic value. [35]

Pharmacological stress uses a vasodilator (adenosine or regadenoson) or dobutamine. Added in the vasodilator method is the administration of i.v. gadolinium contrast, to enhance the perfusion defects that can be seen in ischaemic walls. Using dobutamine requires a similar method like in stress echocardiography, by viewing wall motion abnormalities in ischaemia response. [36]

In CMR the assessment of CAD can be either qualitative (by visual assessment of presence and degree of ischaemia) or quantitative by measuring absolute blood flow. A recent study showed that quantitative analysis had similar diagnostic accuracy (83%) as qualitative (80%) and observers considered a better approach to diagnose CAD using quantitative CMR. [37]

Recent data showed that CMR stress with perfusion in comparison with SPECT and PET showed good diagnostic accuracies, having a sensitivity of 89% (in comparison to SPECT – 88%, and PET – 84%) and a specificity of 76% (in comparison to SPECT – 61% and PET – 81%). Authors also considered that CMR could be a good alternative to PET, having a similar diagnostic accuracy. [38]

Nevertheless, current data shows that perfusion CMR has a better diagnostic performance value than SPECT, as shown in the MR-IMPACT trial [39]. Also, the CE-MARC study showed that CMR had better sensitivities than SPECT (88.7% for men vs. 50.9% for men – SPECT and 85.6% for women vs. 70.8% for women – SPECT) and similar specificities, and better diagnostic accuracies. [40]

The CE-MARC 2 study compared the efficacy of CMR, NICE guidelines and SPECT in reducing the percentage of unnecessary angiographies in patients with suspected angina. The results showed that the CMR strategy determined a lower probability of unnecessary angiographies within 12 months than the NICE guidelines strategy, CMR and SPECT reducing significantly the number of angiographies in comparison to NICE guidelines. [41]

The adverse effects for gadolinium-based contrast agents used in CMR have a low frequency (0.36%), the severe are even less (0.033%), and these adverse effects are more physiological than allergic (most frequently were dyspnea, hypersensitive reactions and emesis). [42].

Similar to SPECT, it had been shown that CMR can have long-term prediction values. Newer technology in CMR measures GLS (global longitudinal strain), this marker can be an independent predictor for long-term major adverse cardiac events (MACE): heart failure hospitalization, myocardial infarction, sustained ventricular tachycardia or death, in pacients with known or suspected coronary artery disease. That means CMR can identify patients with high risk of having dangerous adverse events in the near future because of CAD. [43]

Also, the newest data shows that CMR with quantitative myocardial perfusion mapping can detect coronary microvascular dysfunction separately from CAD, with high AUC-ROC prediction values (0.95 on vessels with MVD) with high sensitivity (90%) and specificity (89%), almost comparable with invasive procedures. [44]

More powerful magnets (3.0 Tesla), although not so widely available, used on CMR machines, have a net superiority over 1.5 Tesla CMR, having a far greater AUC-ROC prediction value (0.963 vs 0.645), sensitivity (90.5% vs. 61.9%) and specificity (100% vs. 61.9%). [45]

Computed tomography

Multidetector row CT systems used in cardiac CT are sufficient enough to visualize coronary anomalies, although this last method is preferable for measuring coronary anatomy and pathology occurring in this matter. There are two methods of using CT in the benefit of diagnosis for CAD: calcium scoring and CTCA (coronary computed tomography angiography).

Calcium scoring uses the principle of identifying coronary calcification, without use of contrast. Any pixel above 130 Hounsfield units is defined as coronary calcification and can be quantified using the Agatston score, which is dependent by the size of the plaque and the radiographic density. [46]

However, there can be identified obstructive coronary lesions which may be not calcified and vice-versa, critically calcified coronary arteries which aren't yet obstructed. Because of this matter, the preferable way to diagnose CAD is CTCA.

The North American Society for Cardiovascular Imaging (NASCI) agreed in their guidelines that patient selection is needed before usage of CTCA. As such:

- because of contrast usage, any patients with known history of severe anaphylactic reactions to contrast, have contraindication to this method;
- patients with history of acute myocardial infarction, severe hypotension, decompensated heart failure or renal impairment have also contraindication to this method;
- pregnant women or patients who are unable to cooperate to the breath-hold instructions are not able to have CTCA. [47]

The method involves usage of a bolus of contrast injected i.v., and after that realizing a coronary angiogram with complementary ECG gating. The ACCURACY trial showed that CTCA in comparison to ICA (invasive coronary angiography) had similar performances in measurements (CTCA sensitivity – 95% vs. 94%, CTCA specificity 83% vs. 83%, CTCA positive predictive value – 64% vs. 48% and CTCA negative predictive value 99% vs. 99%) for diagnosis of CAD with 50%/70% stenosis. [2]

Although the main issue in this non-invasive technique is usage of radiation and scan preparation, another problem is that presence of heavy calcification (objectively measured by an Agatston score > 400) in case of patients with severe CAD lowers the specificity, by creating beam hardening artefacts and excessive image noise. [48]

Analysis of outcome data, such as in the PROMISE trial, showed that patients with suspected CAD who did CTCA had in long-term observation, fewer catheterizations than patients who were functionally tested (using exercise electrocardiography, stress echocardiography or nuclear stress testing) although these patients hadn't any improvement in clinical outcome. [49], and also the SCOT-HEART trial showed that usage of CTCA reduced fatal and non-fatal myocardial infarction but not significantly in patients with suspected CAD. [50]

Improving the current performance in CTCA is possible. One method is measuring tthe fractional flow reserve (CTFFR). Although it is highly time-consuming and requires computer modeling, data shows that usage of CTFFR in CTCA is beneficial, increasing the diagnostic accuracy in comparison to standard CTCA. [51]

Additional usage of β-blockade and nitroglycerin before the exam seem to increase the diagnostic performance [52] and newer data show that CTFFR-CTCA is a safe alternative to ICA with a significantly lower rate of ICA in comparison to functional testing (61% cancelling rate), therefore lowering the clinical cost and having the same clinical outcomes. [53]

Machine-learning (based on a deep learning model) in CTFFR-CTCA seems to also make better the standard procedure, by reclassifying patients with nonsignificant stenosis and raising overall diagnostic accuracy (from 71% to 85%). [54]

CONCLUSION

Currently, non-invasive techniques used to diagnose stable coronary artery disease have a very high accuracy and newer methods seem to be comparable to the gold-standard. The majority of the methods discussed have an optimal performance for patients with PTP between 15-85%, and the future of diagnosis for these patients seem to involve less invasive measures and less radiation by improving the current devices and by usage of machine-learning algorithms.

REVIEW

The Importance of Screening and Early Diagnosis for a Good Outcome in Patients with Colorectal Cancer

Mihai Tanase[1], Jessica O. Cirstea[1], Bianca S. Irava[1], Huzaifa Samie[1]

[1] Central Military Emergency University Hospital "Dr. Carol Davila", Bucharest

Correspondence: Mihai Tanase, drmtanase@yahoo.com

Abstract: Colorectal cancer (CRC) ranks third worldwide in terms of morbidity and second in mortality. In Romania, CRC represents the second leading cause of malignancy, accounting for 13.3% of all diagnosed cancers and associated with a five-year survival rate close to 50%. Despite the availability of effective CRC screening programs proven to reduce incidence and mortality, low participation rates contribute to a high occurrence of advanced disease complications. As a result, bowel obstruction develops in approximately 25% of colorectal cancer cases, significantly worsening patient outcomes. This review aims to highlight the role of screening in reducing the incidence of such complications and to assess the outcomes associated with surgical management of malignant bowel obstruction. A comprehensive review of current literature was conducted, focusing on the incidence, clinical presentation, and management of intestinal obstructions in CRC patients. Emphasis was placed on studies evaluating screening programs, risk factors, and surgical interventions. Data indicate a continuous rise in emergency presentations due to obstructive CRC, correlating with low screening uptake. Early detection through organized screening significantly lowers the risk of obstruction and improves outcomes. Enhanced screening programs and early identification of high-risk individuals are crucial in preventing advanced CRC complications. Timely diagnosis not only reduces emergency surgical interventions but also improves prognosis and overall survival rates.

Keywords: colorectal cancer; screening programs; bowel obstruction; surgical management; early detection

INTRODUCTION

Colorectal adenocarcinoma is a significant global health concern, affecting approximately one million individuals annually and causing nearly 500,000 deaths each year [1-2]. Although rare before the age of 40, its incidence sharply increases after age 45, with most cases diagnosed beyond the age of 50. In Romania, colorectal cancer ranks second among all cancers, accounting for about 13% of cases and a five-year survival rate close to 50% [3-5]. Despite a declining population, Romania saw an increase in cancer incidence from 2011 to 2018, reflecting challenges in healthcare access and prevention [6].

Colorectal cancer is frequently diagnosed at advanced stages due to insufficient screening programs and common risk factors such as smoking, poor diet, and lack of physical activity [7-8]. Additionally, Romania's healthcare system faces significant challenges, including financial and logistical barriers, which hinder early detection and treatment [9-12]. Some studies indicate that approximately 40% of cases occur in the right colon, 31% in the left colon, and 29% in the rectum [13].

The rising incidence of early-onset colorectal cancer has led to changes in screening guidelines, with organizations such as the American Cancer Society lowering the recommended starting age from 50 to 45 years. This shift aims to enhance early detection and improve patient outcomes, though its overall impact remains under evaluation. The optimal screening approach, whether through non-invasive tests followed by confirmatory colonoscopy or direct colonoscopic screening, continues to be debated [14-15].

Effective screening methods such as colonoscopy, flexible sigmoidoscopy, CT colonography, capsule endoscopy, and stool-based detection tests play a crucial role in identifying and removing precancerous lesions, ultimately reducing cancer-related mortality. This paper asserts the importance of increasing awareness and implementing systematic screening programs to curb colorectal cancer incidence and mortality, potentially preventing severe complications such as bowel obstructions [16-19].

MATERIALS AND METHODS

This narrative review systematically examines the existing literature concerning colorectal cancer screening, diagnosis, and the management of acute complications. A comprehensive search was conducted across four prominent electronic databases, namely PubMed, NCBI, Google Scholar, and MDPI. Relevant articles were identified using targeted keywords, such as "colorectal cancer", "screening", "early diagnosis", and "treatment." To ensure the inclusion of contemporary advancements, priority was given to recent publications, primarily from the past five years. Only studies specifically addressing methods for colorectal cancer screening, diagnostic processes, and therapeutic interventions for advanced stages were selected for detailed evaluation in this review.

RESULTS

Screening Methods

Colorectal cancer (CRC) screening is a critical tool in the early detection and prevention of the disease, significantly lowering both incidence and mortality rates. Several screening strategies are available, each with its own benefits and limitations (Figure 1). As technology advances, newer approaches are being incorporated to enhance detection accuracy, patient compliance, and accessibility. The current landscape of CRC screening includes invasive procedures such as colonoscopy, non-invasive stool-based tests, imaging modalities, molecular biomarker assessments, and emerging techniques such as artificial intelligence (AI) and liquid biopsies [20].

Figure 1: Screening guidelines

CRC
- treatment –

**family history of colorectal cancer – screening starting before age 45*
polyps removed – 3 years
personal history of colorectal cancer - 1 year after surgery
radiation to the abdomen or pelvic area to treat a prior cancer – after age 35 or between 3 to 10 years
Crohn's disease or ulcerative colitis – 1 to 3 years
certain genetic syndromes - begin at a young age, more frequently depending on genetic syndrome

Colonoscopy remains the most effective and widely used screening method due to its ability to directly examine the entire colon and rectum. This procedure enables the detection and removal of precancerous polyps, thereby preventing progression to malignancy. With a sensitivity exceeding 95% for advanced neoplasia, colonoscopy is a highly reliable diagnostic and preventive tool. However, its drawbacks include the need for extensive bowel preparation, sedation, and the expertise of trained specialists. Additionally, although rare, complications such as perforation and post-procedural bleeding can occur. Given these factors, adherence to colonoscopy screening remains suboptimal, particularly in average-risk individuals. Nevertheless, it is strongly recommended for high-risk populations, such as those with a personal or family history of CRC or genetic syndromes like Lynch syndrome and familial adenomatous polyposis [21-22].

Flexible sigmoidoscopy is another visualization-based screening tool that examines only the rectum and the lower part of the colon. While it is less invasive and does not require sedation, it is limited in its ability to detect right-sided lesions in the proximal colon. Despite this limitation, studies have shown that sigmoidoscopy reduces CRC incidence and mortality, particularly for left-sided tumors. It is often used in conjunction with stool-based tests to improve overall detection rates [23].

Capsule endoscopy is another innovation being explored for CRC screening. This technique involves swallowing a small, camera-equipped capsule that captures images of the gastrointestinal tract as it moves through the digestive system. Unlike traditional colonoscopy, capsule endoscopy does not require sedation and is non-invasive. However, current challenges include incomplete visualization of the colon, difficulty detecting small lesions, and limitations in image interpretation. Research is focused on enhancing camera resolution, battery life, and image processing technology to improve its effectiveness as a screening tool [24-25].

Computed tomography (CT) colonography, also referred to as virtual colonoscopy, is a radiological screening technique that generates three-dimensional images of the colon and rectum using low-dose CT scans. This non-invasive method eliminates the need for sedation and is generally more tolerable for patients. CT colonography has demonstrated high sensitivity for detecting polyps larger than 10 mm but is less effective for smaller lesions. Unlike conventional colonoscopy, it does not permit biopsy or polyp removal, requiring follow-up colonoscopy for confirmation and intervention when abnormalities are detected. Radiation exposure is another factor that must be considered, particularly for younger individuals undergoing repeated screenings [26].

Blood-based testing has emerged as a promising direction in colorectal cancer (CRC) screening, providing a minimally invasive alternative to traditional methods. These assays aim to detect tumor-associated molecular alterations in circulation, offering improved patient compliance, especially among those hesitant to undergo invasive procedures such as colonoscopy. Among the most studied blood-based tools are circulating tumor DNA (ctDNA) tests, which identify somatic mutations, copy number alterations, and epigenetic changes shed by tumor cells into the bloodstream. ctDNA-based screening has demonstrated high specificity for CRC detection and holds potential for both early diagnosis and post-treatment surveillance. Despite these advances, the sensitivity of ctDNA for detecting early-stage CRC and precancerous adenomas remains limited [27]. This poses a challenge for its application as a standalone screening modality, particularly for detecting lesions before malignant transformation. Additional liquid biopsy strategies, including the analysis of circulating tumor cells (CTCs), exosomal RNA, and methylated DNA, are under active investigation. These approaches aim to enhance detection sensitivity by capturing a broader spectrum of tumor-derived signals, though most remain in the experimental phase and require extensive validation in large-scale prospective studies before being adopted into routine practice. Parallel to blood-based diagnostics, biomarker-driven innovations in stool and urine-based screening have gained traction. Advances in genomics and proteomics have led to the identification of novel molecular signatures associated with CRC, including aberrantly methylated DNA sequences, microRNAs, and tumor-specific proteins. These biomarkers have contributed to the development of next-generation assays that improve the performance of non-invasive tests. The multitarget stool DNA test (sDNA-FIT), which combines fecal immunochemical testing with molecular markers for DNA mutations and methylation, exemplifies this approach and has already been integrated into clinical practice. Nevertheless, ongoing research seeks to refine these assays further, expand biomarker panels, and improve sensitivity and specificity—particularly for early-stage lesions [27-28].

Stool-based screening tests offer an alternative for individuals who prefer non-invasive methods. The fecal immunochemical test (FIT) has largely replaced the traditional guaiac-based fecal occult blood test (gFOBT) due to its improved specificity and sensitivity. FIT detects human hemoglobin in stool samples, reducing the risk of false positives from dietary or upper gastrointestinal sources. This test is typically performed annually and has been associated with a reduction in CRC-related mortality. However, its lower sensitivity for detecting advanced adenomas necessitates frequent retesting. A more advanced stool-based approach, the multitarget stool DNA test (sDNA-FIT), combines FIT with molecular markers to detect genetic mutations and epigenetic changes linked to CRC. This method enhances sensitivity beyond FIT alone and improves the detection of precancerous lesions. However, it has a higher false-positive rate and requires a confirmatory colonoscopy for abnormal findings [29-31].

Artificial intelligence (AI) is increasingly being applied to CRC screening, particularly in colonoscopy and imaging-based methods. AI-enhanced colonoscopy utilizes deep learning algorithms to analyze real-time endoscopic images and improve the detection of adenomas. Studies have demonstrated that AI-assisted colonoscopy increases the identification of subtle mucosal abnormalities, reducing the risk of missed lesions. AI is also being integrated into stool and blood-based screening tests, where machine learning models optimize the interpretation of molecular signatures to improve accuracy. Additionally, computational models incorporating genetic, environmental, and clinical data are being developed to personalize CRC risk assessment and screening recommendations [32-33].

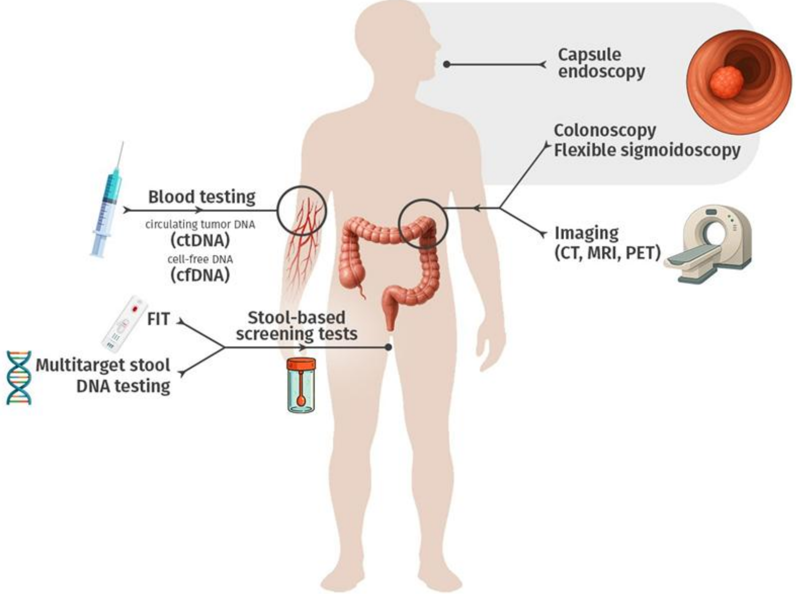
Despite the variety of available screening methods, adherence to CRC screening guidelines remains a significant concern, particularly in populations with limited healthcare access. Socioeconomic barriers, healthcare infrastructure, and patient awareness all play critical roles in screening participation. Efforts to improve accessibility include at-home testing kits, such as FIT and stool DNA tests, which allow individuals to collect and submit samples without visiting a healthcare facility (Figure 2). Increasing public awareness, healthcare provider engagement, and offering personalized screening options based on individual risk factors are essential strategies for enhancing participation in screening programs [34].

Diagnosis Methods

Colorectal cancer (CRC) diagnosis relies on a combination of clinical evaluation, laboratory testing, endoscopic procedures, and imaging techniques to confirm malignancy and determine disease stage. Despite advancements in screening and early detection, a significant proportion of patients are still diagnosed at advanced stages, often presenting with complications such as bowel obstruction. Colonoscopy remains the gold standard for CRC diagnosis, allowing for direct visualization, biopsy, and removal of suspicious lesions during a single procedure. Late-stage detection is associated with poorer outcomes, underscoring the need for timely and effective diagnostic strategies [35].

Imaging modalities, including contrast-enhanced CT scans, magnetic resonance imaging (MRI), and positron emission tomography (PET) scans, play a critical role in staging CRC and evaluating tumor spread. These techniques help determine the extent of local invasion, lymph node involvement, and distant metastases. Accurate staging is essential in guiding treatment decisions, including surgical resection, chemotherapy, radiation therapy, or a combination of modalities for advanced cases. Imaging is particularly important for assessing resectability in metastatic disease, as well as monitoring treatment response in patients undergoing systemic therapy [36].

Figure 2: Screening methods



Despite these diagnostic advancements, many CRC cases are still identified at later stages when symptoms become severe. One of the most common emergency presentations of advanced CRC is bowel obstruction, occurring in approximately 20% of cases. This complication results from tumor-induced narrowing of the intestinal lumen, leading to symptoms such as severe abdominal pain, bloating, nausea, vomiting, and the inability to pass stool or gas. Bowel obstruction often necessitates urgent medical intervention, with many patients requiring emergency surgery to relieve the blockage and resect the affected segment of the bowel. Compared to elective surgery for early-stage CRC, emergency surgical interventions are associated with increased postoperative complications, prolonged hospital stays, and higher mortality rates. The occurrence of bowel obstruction as an initial manifestation of CRC highlights the ongoing challenges in early detection, particularly among individuals who do not undergo regular screening. Patients presenting with obstruction often have advanced tumors that limit treatment options, negatively impacting prognosis. Research has shown that individuals diagnosed with obstructive CRC have lower survival rates compared to those diagnosed through routine screening, emphasizing the need for widespread and consistent preventive measures [37-38].

Treatment

For patients diagnosed with early-stage CRC, particularly stage I and stage II, surgical resection is the primary treatment. In stage I, where the tumor is confined to the bowel wall without lymph node involvement, removal of the affected segment of the colon with regional lymphadenectomy is typically curative. The preferred surgical approach may be open or laparoscopic colectomy, with the latter offering benefits such as reduced postoperative recovery time and lower complication rates. In stage II disease, the cancer has penetrated the muscular layer of the colon but has not spread to regional lymph nodes. Surgery remains the standard of care, but adjuvant chemotherapy may be considered in cases where high-risk pathological features are present, including T4 tumors, lymphovascular invasion, perineural invasion, poor differentiation, or inadequate lymph node sampling. The decision to administer chemotherapy is individualized, considering both the potential survival benefit and the risk of treatment-related toxicity [39-41].

Management of stage III CRC, where the cancer has spread to regional lymph nodes, involves a multimodal approach integrating surgery and systemic chemotherapy. The primary surgical treatment is colectomy with complete mesocolic excision and lymphadenectomy to achieve optimal oncologic outcomes. Adjuvant chemotherapy is recommended in nearly all cases to eliminate micrometastatic disease and reduce recurrence risk. Standard chemotherapy regimens include FOLFOX (5-fluorouracil, leucovorin, and oxaliplatin) and CAPOX (capecitabine and oxaliplatin), with treatment duration typically spanning six months. In patients who cannot tolerate oxaliplatin, fluoropyrimidine monotherapy remains an option, though with slightly lower efficacy [39-40].

Stage IV CRC is characterized by distant metastases, most commonly involving the liver, lungs, or peritoneum. In these cases, systemic therapy is the cornerstone of treatment, intending to prolong survival and maintain quality of life. Chemotherapy regimens such as FOLFOX and FOLFIRI (5-fluorouracil, leucovorin, and irinotecan) are frequently utilized, often in combination with targeted agents. Bevacizumab, an anti-VEGF monoclonal antibody, is commonly added to chemotherapy to inhibit tumor angiogenesis, particularly in patients with RAS-mutant tumors. In contrast, EGFR inhibitors such as cetuximab and panitumumab are used in RAS-wild type tumors, demonstrating improved response rates when combined with chemotherapy. Molecular profiling, including assessment of KRAS, NRAS, and BRAF mutations, is crucial in guiding treatment selection, as tumors harboring certain mutations exhibit resistance to EGFR-targeted therapies. Additionally, immunotherapy has emerged as a novel treatment option for patients with microsatellite instability-high (MSI-H) or deficient mismatch repair (dMMR) tumors, with checkpoint inhibitors such as pembrolizumab and nivolumab demonstrating promising efficacy in this subset of patients [39-40, 42-43].

A significant proportion of CRC cases, particularly those diagnosed at advanced stages, present with bowel obstruction, a life-threatening complication resulting from tumor-induced luminal narrowing. This condition manifests as severe abdominal pain, nausea, vomiting, and bowel distension, often necessitating urgent medical intervention. The management of bowel obstruction is guided by the patient's overall prognosis, performance status, and treatment goals. In patients with potentially resectable disease and good functional status, surgical intervention, such as resection of the obstructing tumor or creation of a diverting ostomy, may be performed to restore bowel function and facilitate further oncologic treatment. However, in patients with widespread metastases or poor surgical candidacy, non-surgical approaches such as endoscopic stenting are preferred. Self-expanding metal stents (SEMS) can be placed to relieve obstruction and maintain luminal patency, serving as either a bridge to surgery in operable patients or a palliative measure in those with unresectable disease. While SEMS placement offers symptom relief with a lower risk of perioperative morbidity, potential complications include stent migration, re-obstruction, and perforation, particularly in patients receiving anti-angiogenic therapy [44-46].

Medical management plays an essential role in symptom control for patients with bowel obstruction. Corticosteroids may be administered to reduce tumor-associated edema and improve bowel patency. Antiemetics, including dopamine antagonists and serotonin receptor antagonists, are used to alleviate nausea and vomiting, while opioid and non-opioid analgesics help manage pain. In cases where bowel function cannot be restored, a venting gastrostomy tube may be placed to decompress the stomach and relieve symptoms of persistent vomiting. Total parenteral nutrition (TPN) may also be considered for select patients to prevent malnutrition when enteral feeding is not feasible. Given the complex nature of malignant bowel obstruction, a multidisciplinary team approach, including oncology, gastroenterology, surgery, and palliative care specialists, is necessary to ensure comprehensive management tailored to the patient's individual needs [47].

DISCUSSION

Colorectal cancer (CRC) remains a major health challenge despite advances in screening, diagnosis, and treatment. A key issue is the persistent late-stage diagnosis, which is often associated with complications such as malignant bowel obstruction. The need for improved screening adherence and the integration of novel technologies to enhance early detection is evident, as early intervention significantly improves survival outcomes. However, real-world implementation of screening recommendations remains suboptimal due to accessibility issues, patient reluctance, and limitations of existing tests.

The effectiveness of CRC screening depends on balancing sensitivity, specificity, patient compliance and healthcare system feasibility. While colonoscopy is the most definitive method, its invasiveness and preparation requirements often deter patients. Non-invasive alternatives like fecal immunochemical tests (FIT) and stool DNA testing provide practical options but require frequent testing and have limitations in detecting precancerous lesions. CT colonography offers another alternative but lacks the ability to remove polyps during the procedure. The future of CRC screening may lie in risk-adapted strategies that personalize screening intervals and methods based on genetic predisposition, lifestyle factors, and emerging biomarkers.

A significant portion of CRC cases are detected at advanced stages, often when symptoms such as bowel obstruction arise. These cases require urgent medical intervention, typically involving surgery or endoscopic stenting. While self-expanding metal stents (SEMS) are increasingly used for temporary relief, their risks, including perforation and migration, necessitate careful patient selection.

Addressing late-stage CRC diagnosis requires increased awareness of early warning signs, improved access to screening programs, and adherence to recommended screening guidelines. Healthcare providers play a crucial role in recognizing potential symptoms and encouraging high-risk individuals to undergo regular screening. Strategies to improve early detection include expanding non-invasive screening options, utilizing risk-based stratification models to identify individuals at greater risk, and integrating emerging technologies such as liquid biopsy and artificial intelligence-assisted diagnostics. By strengthening early detection efforts, the burden of late-stage CRC and its associated complications, including bowel obstruction, can be significantly reduced, leading to better patient outcomes and improved survival rates.

Disparities in CRC outcomes highlight the need for broader access to screening and timely treatment. Socioeconomic barriers, healthcare infrastructure disparities, and patient education gaps contribute to late-stage diagnoses. Efforts to integrate artificial intelligence (AI) in colonoscopy and risk prediction models could enhance detection accuracy and optimize screening protocols. AI-assisted imaging analysis has demonstrated the ability to improve adenoma detection rates, reducing missed lesions and potentially lowering CRC incidence.

The treatment of CRC is continually evolving, with research focusing on optimizing multimodal therapeutic strategies to improve survival and quality of life. While surgery remains the foundation for early-stage disease, systemic therapy plays a critical role in advanced CRC, particularly with the integration of targeted agents and immunotherapy. The management of complications such as malignant bowel obstruction requires a patient-centered approach, balancing aggressive interventions with supportive care to maintain comfort and dignity. Ongoing clinical trials continue to explore novel therapeutic approaches, including next-generation targeted therapies and personalized medicine strategies, which aim to refine treatment paradigms and improve outcomes for patients diagnosed with colorectal cancer.

CONCLUSION

While significant progress has been made in CRC screening, diagnosis and treatment, challenges remain in optimizing early detection, improving treatment outcomes for advanced-stage disease and addressing disparities in care. A multidisciplinary approach integrating surgery, systemic therapy and supportive care remains crucial in managing CRC across different disease stages. Ongoing research into AI, molecular profiling and liquid biopsies holds promise for further refining CRC management strategies and improving patient outcomes. Continued efforts to enhance screening adherence, personalize treatment approaches and expand access to novel therapies will be key in reducing the global burden of colorectal cancer.

Conflicts of interest and sources of funding

The authors declare no conflict of interest. No artificial intelligence automatically generated text was inserted in this manuscript, and no image was previously published in another journal or is under consideration of being published elsewhere. This research received no external funding.

Authors' contribution

Conceptualization- M.T., J.C. and B.I.; methodology - M.T.; investigation - M.T., J.C. and B.I.; writing of the manuscript- M.T. and J.C.; review, editing - M.T., J.C. B.I. and H.S; data curation - J.C. All authors have read and agreed to the published version of the manuscript.

Ethics approval and consent to participate

The study was conducted under the Declaration of Helsinki. The research was conducted under ethical guidelines and regulations, ensuring compliance with all necessary protocols.

Patient consent for publication

Written informed consent has been obtained from the patient to publish this paper.

Abstract: Cardiovascular-kidney-metabolic (CKM) syndrome describes the complex, bidirectional interplay among cardiovascular, renal, and metabolic dysfunctions, where impairment in one system accelerates decline in the others. This interconnected pathophysiology significantly elevates the risk and progression of heart disease, particularly heart failure, through mechanisms involving insulin resistance, systemic inflammation, neurohormonal activation, and endothelial dysfunction. In this context, therapeutic strategies targeting heart disease must address the multifaceted drivers of CKM. Recent advances highlight the need for an integrated, patient-centered approach that combines lifestyle interventions with pharmacological treatments tailored to individual cardiovascular risk. While foundational therapies such as RAAS inhibitors and statins remain essential, novel agents now offer additional prognostic and quality-of-life benefits. SGLT2 inhibitors have emerged as a cornerstone therapy, improving outcomes in heart failure with both preserved and reduced ejection fraction, independent of glycemic control. GLP-1 receptor agonists and dual GLP-1/GIP agonists like tirzepatide demonstrate cardiometabolic and renal protection, while finerenone shows promise in diabetic kidney disease and several heart failure phenotypes. These therapies not only target glycemic control but also reduce cardiovascular mortality, hospitalizations, and renal decline. Optimizing cardiovascular outcomes in CKM syndrome requires early, multifactorial therapeutic intervention, informed by evolving evidence and a deeper understanding of the heart–kidney–metabolism axis.

Keywords: heart failure, diabetes mellitus, obesity, chronic kidney disease, GLP-1 receptor agonists, SGLT2 inhibitors, mineralocorticoid-receptor antagonists, finerenone, cardiovascular-kidney-metabolic syndrome

INTRODUCTION

Heart disease is frequently observed in patients with CKM syndrome. There is a pathophysiological interplay between the cardiovascular, renal, and metabolic systems, where dysfunction in one organ can exacerbate impairment in others, which substantially increases the risk of developing heart failure. Patients with CKM syndrome usually present with overlapping conditions as type 2 diabetes, chronic kidney disease, and atherosclerotic cardiovascular disease, all of which contribute to functional and structural cardiac dysfunction.

Heart disease and cardiovascular mortality represent the main drivers of prognosis in all CKM syndrome comorbidities. Hence, special consideration should be directed toward understanding pathophysiological mechanisms through which all these metabolic risk factors converge toward cardiovascular impairment. Additionally, emphasis should be placed on the early and appropriate initiation of the right medication for the right patient, tailored to the estimated individual risk, particularly concerning the novel drug classes that have demonstrated beneficial effects across all components of the CKM syndrome: GLP1 receptor agonists, SGLT2 inhibitors, and the non-steroidal mineralocorticoid receptor antagonist finerenone.

This review emphasises the role of the heart in the CKM spectrum, with particular interest in the therapeutic implications.

GLP-1 RECEPTOR AGONISTS

GLP-1 (glucagon-like peptide-1) is a natural hormone mainly released by intestinal L enteroendocrine cells residing in the distal jejunum, ileum, and colon, as a result to oral glucose intake. GLP-1 is classified as an incretin hormone because it stimulates insulin release from beta pancreatic cells, inhibits the release of glucagon and, along with that, hepatic glucose output, and reduces the rate of gastric emptying and promotes satiety by central appetite suppression. GLP-1 has a very short half-life of approximately 2 minutes, being quickly cleaved by dipeptidyl peptidase IV (DPP-4), a widely expressed enzyme, thereby limiting the strong insulin secretagogue effect of this hormone [1–3].

Owing to the very short half-life, the molecule of GLP-1 is not suitable for an adequate therapeutic agent. Nevertheless, researchers developed molecules capable of being adequate therapeutic agents: inhibitors of DPP-4, which are capable of prolonging the effects of natural GLP-1, and molecules that represent long-acting GLP-1 receptor agonists [1].

Apart from pancreas, GLP-1 receptors are expressed on various types of cells throughout the body and the finding of this widespread localization of receptors led to studies that demonstrated multiple effects beyond the well-known incretin actions, the so-called “pleiotropic effects”: in central nervous system, being involved in the regulation of appetite, in the cardiovascular system, being expressed both in cardiomyocytes and vascular cells, in the musculoskeletal system, gastrointestinal tract, regulating the motility or secretion, interfering in the gut-brain axis, in adipose tissue influencing fat metabolism through interaction with leptin, in kidneys at multiple levels (arterial and arteriolar smooth cells, glomerulus, juxtaglomerular cells, proximal tubule), modulating renal function both directly by altering glomerular hemodynamics and indirectly through less known direct interactions between gastrointestinal system and kidneys known as gut-renal axis [3–7]. Even in beta pancreatic cells, besides altering insulin or glucagon levels, the stimulation of GLP-1R could enhance beta-cell proliferation, inhibit apoptotic pathways, and induce expansion of islet mass [4].

Considering that diabetes mellitus and obesity serve as risk factors in the context of cardiovascular diseases, the effects of GLP-1 receptor agonists on the cardiovascular system are, to a considerable extent, mediated through modulation of these metabolic conditions.

Regarding their role as antidiabetic medications, all GLP-1RAs proved effective in glycemic control by reliably reducing fasting plasma glucose and HbA1c (up to a reduction of 56.2 mg/dl FPG levels and 2.1% for HbA1c levels, respectively) [8].

Obesity is strongly associated with the development of T2DM as excessive adipose tissue, particularly visceral fat, contributes to insulin resistance [9]. The central downregulation of appetite, accompanied by slowing the gastric evacuation, which induces a feeling of fullness, facilitates the reduction of overall calorie intake and the maintenance of a favorable long-term energy balance [3]. Large meta-analyses of the available RCTs proved that GLP-1 RA are effective in inducing weight loss and a reduction in the body mass index and in the waist circumference [8,10].

Conversely, an increasing body of evidence suggests that GLP-1RAs exert direct beneficial effects on various components of the cardiovascular system, independently of their impact on glycemic regulation and weight control.

As far as cardiomyocytes are concerned, the presence and the exact extent of GLP-1R expression are unclear, corroborated by limited evidence regarding the cellular localization of GLP-1R protein [11]. However, in cellular and animal models, besides metabolic effects, which could indirectly improve cardiac function, there is evidence that GLP-1 could restore crucial signaling pathways that could be altered by external stressors [7]. For example, GLP-1 could ameliorate the extent of ischemia-reperfusion injury by activating specific signaling pathways and inhibiting cardiomyocyte apoptosis [3]. Moreover, GLP-1 signaling is involved in reducing hyperglycemia-induced apoptosis of the cardiomyocytes by optimizing the signaling pathways from the sarcoplasmic reticulum and in lowering the extracellular matrix remodeling [12].

There is also important evidence that GLP-1 receptor stimulation influences various pathogenic mechanisms that are involved in atherogenesis. First of all, GLP-1 can mitigate endothelial dysfunction by inducing NOS-mediated vasodilation and by limiting the formation of advanced glycosylation end-products [3,13]. Additionally, GLP-1 is involved in improving lipid metabolism at several levels: with respect to gene expression, it downregulates genes of lipogenic enzymes and upregulates genes of lipolytic enzymes, reduces lipotoxicity by lowering lipid peroxidation, stimulates fatty acid oxygenation, inhibits HMG-CoA reductase and lowers cholesterol levels, ameliorates hepatic steatosis, lowers serum triglyceride levels and even reduces intestinal lipid absorption [3,14]. There are also described effects of enhanced cholesterol efflux from foam cells or suppression of foam cell formation [13]. Even an anti-inflammatory pathway is proposed with the downregulation of genes involved in inflammation and oxidative stress. Moreover, GLP-1 promotes an atherosclerotic plaque remodeling towards stabilization by reduction of matrix metalloproteinases (MMP), proteolytic enzymes involved in weakening of plaque fibrous caps and in increasing the risk of rupture [3,13].

GLP-1RA proved effects of blood pressure reduction both in preclinical and clinical studies, by as much as 6 mmHg (as it was found in DURATION-1 trial) [11,15]. There are several mechanisms possibly involved in this effect: the capacity of GLP-1RA to counteract the sympathetic nervous system hyperactivation, both at the central and peripheral nervous system level, the improvement in the endothelial function and therefore in vasodilation, and the possible effect on renal tubular mechanisms by increased natriuresis, which was observed in experimental models of hypertension [16,17]. The effect of lowering blood pressure was consistent throughout the entire spectrum of renal function, from normal to severely reduced [18].

Diabetes affected individuals are at high risk of chronic kidney disease (CKD) (as many as 40% diabetic patients develop chronic kidney disease), diabetic nephropathy representing the leading cause of chronic kidney disease worldwide. However, in the CKD population, cardiovascular events constitute the primary contributor to mortality, due to enhanced atherosclerosis, arterial and valvular calcification, and amplification of myocardial fibrosis [19]. There is a clear rationale that reducing both the risk and progression of chronic kidney disease could play a pivotal role in decreasing the burden of cardiovascular complications in diabetic patients.

Apart from indirect beneficial effects of glycemic control, weight loss and blood pressure reduction upon renal function, there are described direct effects: increased natriuresis and diuresis, at least partially explained by inhibiting sodium-hydrogen exchanger 3 in proximal tubular cells, anti-inflammatory effects by inhibition of cytokine production and chemotactic recruitment of inflammatory cells, free-radical scavenging effects and direct glomerular hemodynamic effects [5,17,19].

Another pathophysiological mechanism seemingly targeted by this therapeutic class is the modulation of the renin–angiotensin–aldosterone system, as there was been proven that GLP-1RA could induce a decrease in plasma levels of renin and angiotensin II. The effect of lowering the activity of this system could contribute to the effect of lowering blood pressure, the enhanced natriuresis, and could influence glomerular hemodynamics by vasodilation of the efferent arteriole and reduction of glomerular capillary pressure [18].

Beyond the pathophysiological effects demonstrated at the experimental level, the clinically relevant renoprotective effects include the reduction of albuminuria and, as evidenced by several studies, a reduction in eGFR decline [18,20].

Transitioning from experimental models and pathophysiological mechanisms to clinical evidence, GLP-1RA use in practice is supported by results from representative large-scale cardiovascular outcome trials. These studies have positioned GLP-1 receptor agonists as a distinct class among antidiabetic medications, with benefits that go beyond mere glycemic regulation.

There are 8 cardiovascular outcomes randomized controlled trials (CVOTs) for 7 different GLP-1RA (lixisenatide, liraglutide, semaglutide s.c., oral semaglutide, exenatide, albiglutide, dulaglutide, efpeglenatide) which included type 2 diabetic patients with high cardiovascular risk or previous cardiovascular disease. Four different GLP-1RAs, namely liraglutide, semaglutide s.c., dulaglutide, and efpeglenatide, proved efficient in reducing a composite end-point of major adverse cardiac events MACE (comprising cardiovascular death, non-fatal myocardial infarction, and non-fatal stroke)[21]. However, analyzing the hazard ratio for individual components of MACE, there is a clear heterogeneity between these molecules. A meta-analysis which included all 8 RCTs, comprising a total of 60.080 patients (72.4% having established cardiovascular disease), concluded that GLP-1RA class reduce MACE by 14% (HR = 0.86, 95% CI 0.79-0.94, P = 0.006), with significant effects on the risk of cardiovascular death by 13% (P = 0.016) and nonfatal stroke by 16% (P = 0.007) [22]. Another meta-analysis, which included the same RCTs but ELIXA (the RCT examining lixisenatide), because lixisenatide is a short-acting agent that raised concerns regarding the lack of sustained GLP-1 inhibition in patients, GLP-1 RA proved effective in reducing MACE by 14% (HR 0.86 [95% CI 0.80–0.93]; p<0.0001), cardiovascular death by 13% (HR 0.87 [0.80–0.94]; p=0.0010), stroke by 17% (0.83 [0.76–0.92; p=0.0002), and, in addition to the other meta-analysis, myocardial infarction by 10% (0.90 [0.83–0.98]; p=0.020) [23]. Additionally, both meta-analyses proved a significant 12% reduction in all-cause mortality [22,23].

Table 1: Major CVOTs of GLP-1RA [21] (Although promising results, albiglutide was withdrawn from the market by the manufacturer due to commercial reasons)

Taking into account the various pleiotropic effects of GLP-1, there has emerged the hypothetical idea of using GLP-1RA in individuals without diabetes. In 2023, the results of the SELECT trial were published, a randomized controlled trial that included overweight patients (BMI>27 kg/m^2) with a history of cardiovascular disease but without diabetes. Subcutaneous semaglutide proved efficient, compared to placebo, in reducing MACE by 20% (HR 0.80 [0.72 to 0.90]; p<0.001), mainly driven by a statistically significant reduction of myocardial infarction risk by 28% [24].

These solid results, from large, reputable RCTs, have been translated into guideline recommendations. According to the 2024 ESC Guidelines for the management of chronic coronary syndromes and the 2023 ESC Guidelines for the management of cardiovascular disease in patients with diabetes, GLP-1RAs have a class I (level of evidence A) recommendation in patients with diabetes mellitus type 2 and history of atherosclerotic cardiovascular disease to reduce incident MACE [25,26]. This recommendation stands regardless of the baseline or target HbA1c or any other antidiabetic medications the patient may be taking. Additionally, consistent with the SELECT trial, the 2024 ESC Guidelines for the management of chronic coronary syndromes (CCS) included a IIa (level of evidence B) recommendation for the utilization of subcutaneous semaglutide in overweight (BMI > 27 kg/m^2) CCS patients to mitigate the risk of cardiovascular mortality and myocardial infarction [24,25].

As far as kidney outcomes are concerned, there is an RCT specifically designed to assess renal endpoints. The FLOW trial included 3533 patients with type 2 diabetes mellitus and CKD (defined as eGFR 50-75 ml/min/1.73m^2 and macroalbuminuria UACR >300 mg/g or eGFR 25-50 ml/min/1.73m^2 and albuminuria UACR >100 mg/g) and compared subcutaneous semaglutide with placebo. The results showed that subcutaneous semaglutide reduced the risk of a primary outcome (defined as a composite of major renal adverse events comprising new onset of kidney failure, a reduction of eGFR of at least 50% from baseline, or death from kidney or cardiovascular-related causes) with 24% (HR 0.76; [0.66 to 0.88]; p=0.0003) [27]. There is also some evidence toward improving kidney outcomes emerging from the pivotal CVOTs of GLP-1RA and from the meta-analyses which assessed them, but with a lower degree of statistical power as the conclusions are derived from secondary outcomes or exploratory assessments, and the renal benefits were demonstrated through the reduction in the progression of albuminuria, with fewer effects observed on hard end-points [21].

With regard to heart failure, the aforementioned meta-analyses reported a 10% risk reduction of heart failure hospitalizations, but this result was driven only by the reduction reported in the AMPLITUDE-O trial, which investigated efpeglenatide [21–23]. As a result, this outcome could not be generalized as a class effect.

2 clinical trials specifically investigated GLP-1RA in HFrEF patients: FIGHT and LIVE. Neither of the two trials demonstrated the beneficial effects of GLP-1 receptor agonists in patients with HFrEF. Notably, the LIVE trial even raised concerns regarding a potential trend toward an increased risk of mortality, ventricular arrhythmias, and atrial fibrillation [21,28]. In terms of HFpEF, two complementary RCTs were published, which investigated subcutaneous semaglutide in obese patients (BMI>30 kg/m^2) without DM (STEP-HFpEF) and with DM (STEP-HFpEF DM). In both trials, there are reported similar results: significant reductions in primary end-points such as a reduction of 7.8 points in Kansas City Cardiomyopathy Questionnaire (KCCQ) (95% CI [4.8 to 10.9]; P<0.001) in STEP-HFpEF and a reduction of 7.3 points in KCCQ in STEP-HFpEF DM (95% [CI] [4.1 to 10.4]; P<0.001) and an average of 10.7% reduction in body weight (95% CI [−11.9 to −9.4]; P<0.001) in STEP-HFpEF and 6.4% reduction in body weight (95% CI [−7.6 to −5.2]; P<0.001) in STEP-HFpEF DM. There are also reported significant results concerning secondary end-points, such as an average improvement of 20.3 m at 6-minute walk distance (95% CI [8.6 to 32.1]; P<0.001) in STEP-HFpEF and 14.3 m (95% CI [3.7 to 24.9]; P=0.008] in STEP-HFpEF DM, respectively. Essentially, these two trials proved that semaglutide improves symptoms and exercise capacity in obese HFpEF patients with or without type 2 DM, but neither study was powered enough to evaluate the influence on hard clinical events, such as heart failure-related hospitalizations or urgent hospital visits [29,30]. It has been suggested that the clear weight reduction effect had a major contribution to the improvement of symptoms and exercise capacity in these patients [21].

Tirzepatide has recently emerged as a new star in the GLP-1 modulation field, being the latest discovered molecule in this class. More specifically, tirzepatide is a dual agonist that acts both on the receptors of GLP-1 and the receptors of GIP (glucose-dependent insulinotropic polypeptide). GIP represents another incretin hormone, naturally released by K-cells of the upper small intestine. Tirzepatide was validated as an effective antidiabetic medication (up to 2.4% reduction in HbA1c), as proved in the series of trials SURPASS 1-5, when tirzepatide was subsequently compared to placebo, or to active comparators, such as semaglutide, to which it was shown to be non-inferior or insulin degludec, to which it was shown to be superior in terms of glycemic control [31]. In terms of weight management, in SURMOUNT 1-4 clinical trials, tirzepatide proved a potent effect, with a mean weight loss of up to 26% [32]. In a recent network meta-analysis, compared to GLP-1 RA, tirzepatide proved higher efficacy in terms of glycemic control and weight control, probably owing to the dual incretin action [8]

Besides direct effects in the metabolic pathway, the SUMMIT trial yielded noteworthy findings in both the cardiovascular and, to some extent, the renal pathways of CKM syndrome. It included 731 obese patients (BMI over 30 kg/m^2) with HFpEF (LVEF of at least 50%), regardless of their diabetes status, who were randomized to receive either tirzepatide or placebo. The trial yielded positive results with regard to the both primary end-points: first one representing a composite end-point formed by death from cardiovascular causes or a worsening heart failure event (hazard ratio, 0.62; 95% confidence interval [CI], 0.41 to 0.95; P=0.026), a result mainly driven by a reduction in worsening heart-failure events (hazard ratio, 0.54; 95% CI, 0.34 to 0.85), and the second one a reduction in KCCQ score, with a between-group difference at the end of the study of 6.9 (95% CI [3.3 to 10.6]; P<0.001). There was no difference in cardiovascular death [33]. Therefore, for the first time, the SUMMIT trial offered evidence derived from an RCT that influencing metabolic pathways with tirzepatide, regardless of diabetes diagnosis, we could influence hard cardiovascular end-points.

An interesting, recently published subanalysis of the SUMMIT trial found that the beneficial effects of tirzepatide upon worsening heart failure events or various metrics pertaining to functional capacity or quality of life are not influenced by the presence or absence of CKD, namely, eGFR does not seem to influence the effects on major adverse heart failure outcomes. In a head-to-head comparison pertaining to the primary composite end-point of death from cardiovascular causes or a worsening heart failure event, tirzepatide showed a larger absolute risk reduction in the CKD group (preventing 3.6 primary endpoint events for 100 patients treated for 1 year) compared to the group without CKD (preventing 1.6 primary endpoint events for 100 patients treated for 1 year). This may probably be an effect at least partially explained by the larger global risk of heart failure events in CKD patients. Moreover, tirzepatide seems to significantly ameliorate glomerular function at 52 weeks (+2.9 [95% CI: 0.9-4.9]; P = 0.004), an effect which proved constant throughout the broad spectrum of baseline eGFR (between 15 ml/min/1.73 m^2 and 70 ml/min/1.73m^2), as well as UACR at 24 weeks (−25%; 95% CI: −35.5% to −12.7%; P < 0.001) [34].

Although we have a very probable class effect of GLP-1RA in reducing MACE and unique evidence for tirzepatide in influencing hard end-points in HFpEF, currently, there is no direct evidence from RCTs that the dual GLP-1R/GIPR agonist reduces MACE. There exists an ongoing trial (SURPASS-CVOT) which currently evaluates the effect of tirzepatide in comparison to dulaglutide on MACE in patients with type 2 diabetes mellitus.

In general, GLP-1RAs are considered relatively well-tolerated medications, and evidence derived from clinical trials supports their effectiveness. However, there are described side effects such as hypersensitivity reactions (including, in rare cases, anaphylactic shock), a hypothetical enhanced risk of C-cell thyroid neoplasm (based on animal studies and theoretical risk), gastrointestinal adverse effects (such as nausea or vomiting, especially during initiation or dose escalation, increased ileus risk), an increased risk of cholelithiasis, cholecystitis and pancreatitis, and concerns of increased pancreatic cancer risk emerging from observational studies. Generally, gastrointestinal adverse effects are the most common and the most frequent cause of drug discontinuation [35].

SGLT2 INHIBITORS

SGLT2 inhibitors were created to target the SGLT2 transporter, a protein mainly located in the first segment of the proximal convoluted tubule, which is responsible for the absorption of 90-97% of the filtered glucose. The reabsorption of one molecule of glucose is coupled with one sodium ion, the latter being transported along the transmembrane concentration gradient created by the Na/K ATP-ase pump [36]. The residual glucose that escapes reabsorption is transported via SGLT1, which is located in the more distal parts of the proximal convoluted tubule. In case of SGLT2 blockage, SGLT1 could partially compensate for its effects, with only 50-60% of the filtered glucose excreted in the urine [37]. Although SGLT2 is mainly located in the kidney, it is also found in the brain, liver, thyroid, and striated muscle [36,37].

The development of SGLT2 inhibitors was inspired by phlorizin, a naturally occurring compound known to be a SGLT2 inhibitor, with the therapeutic objective of promoting natriuresis and glycosuria in order to obtain glycemic control [37]. In the context of efforts to preserve the biologically active properties of phlorizin, while also improving its oral bioavailability and stability, a series of novel molecules were developed: canagliflozin, dapagliflozin, empagliflozin, and ertugliflozin. Moreover, a dual inhibitor that blocks both SGLT1/SGLT2, namely sotagliflozin, was approved, which adds the effect of delaying intestinal glucose absorption by inhibiting SGLT1 at this level [37,38]. All molecules share very attractive pharmacologic properties: optimal oral absorption, once-daily administration as a result of the long half-life, metabolism occurring primarily in the liver, reduced renal clearance, and absence of clinically significant drug interactions [37].

Throughout studies, SGLT2 inhibitors have shown only modest effectiveness with regard to glycemic control, with reductions in HbA1c levels within the range of 0.5-1% [36,39]. Despite continuous glycosuria, inhibition of SGLT2 reduces insulin release and increases glucagon levels, which stimulates gluconeogenesis besides activation of lipolysis and lipid oxidation [40]. Similar to GLP-1 receptor agonists, and constituting an important observation for the largely overweight type 2 diabetes population, it was observed that SGLT2 inhibitors also exert a weight-reducing effect. This effect was observed to be approximately 2 to 4 kg, a consistent and durable reduction documented across all studies and for all molecules. To refer to specific figures, the inhibition of glucose reabsorption at the nephron level causes a loss of 75 g of glucose per day, which means nearly 300 kcal per day. It would be expected that a yearly weight loss of 10 kg, which is much more than was noted in clinical studies [40]. There are proposed mechanisms for this discrepancy between theory and practice, and the most prominent one is compensatory hyperphagia induced by a reduction in leptin, a hormone released by adipose tissue which inhibits appetite at a central level [40,41].

After the finding that rosiglitazone, a thiazolidinedione, is associated with an increased risk of adverse cardiovascular events, the scientific community requested that the new SGLT2i need to undergo cardiovascular outcome trials in order to prove their safety, similar to the aforementioned GLP-1RA.

The EMPA-REG OUTCOME trial tested empagliflozin in over 7000 patients with established cardiovascular disease and proved that this SLGT2i is associated with a significant 14% (HR 0.86; 95% confidence interval [CI], 0.74–0.99; p=0.04) reduction in the risk of major adverse cardiovascular events, a 32% reduction of all-cause mortality (HR, 0.68; 95% CI, 0.57–0.82]; p<0.001), and a 35% reduction of HF hospitalization risk (HR, 0.65; 95% CI, 0.50–0.85; p=0.002) [42,43]. Similarly, the DECLARE TIMI trial, for dapagliflozin, showed non-inferiority to placebo with respect to MACE (p<0.001) and a reduction with 17% of the risk for cardiovascular death or hospitalization for heart failure (HR, 0.83; 95% CI, 0.73-0.95; p=0.005) [42,44]. The CANVAS trial, for canagliflozin, showed a reduction with 14% of the combined risk of death from cardiovascular causes, nonfatal myocardial infarction, or nonfatal stroke (HR, 0.86; 95% CI, 0.75 to 0.97; P<0.001 for noninferiority; P=0.02 for superiority) [42,45]. Ultimately, the VERTIS trial, which studied ertugliflozin, found a significant reduction in the risk of heart failure hospitalizations [42]. Based on these preliminary studies, the ESC guidelines for the management of heart failure mention a class I indication for the utilization of SGLT2i in diabetic patients at high risk for CV events to reduce the risk of hospitalization for heart failure events, MACE, end-stage renal dysfunction, or cardiovascular death [46].

These initial trials prompted the conduction of future dedicated trials in order to establish a potential role of SGLT2i in the management of heart failure patients.

The further DAPA-HF trial proved to be a pivotal study, which paved the way for the actual large indications of SGLT2i in heart failure with reduced ejection fraction (HFrEF). This trial included 4744 patients with II-IV HYHA class heart failure, with an ejection fraction of less than 40% and proved that dapagliflozin (10 mg single dose) is associated with the reduction of a primary composite outcome of cardiovascular death, HF hospitalizations, and worsening HF (HR, 0.74; 95% CI, 0.65 to 0.85; P<0.001), with all components of this composite outcome being positively and significantly influenced. This trial also found that the effect is not influenced by the diabetic status of the patient [42,47].

For empagliflozin, the EMPEROR-Reduced trial showed similar results: a reduced composite outcome of cardiovascular death and HF hospitalizations (HR, 0.75; 95% CI, 0.65–0.86; p<0.001), similarly independent of the diabetic status of the patient. In the case of empagliflozin, the effect on the primary outcome was mainly driven by the reduction of the rate of HF hospitalizations, as the reduction of cardiovascular death proved to be non-significant [42,48]. A meta-analysis of these 2 landmark trials found significant reductions in all-cause death (pooled HR 0.87, 95% CI 0.77-0.98; p=0.018) and in cardiovascular death (pooled HR 0.86, 0.76-0.98; p=0.027) [49].

These findings have been incorporated into guideline recommendations, as both the ESC guidelines and the ACC/AHA guidelines on heart failure mention dapagliflozin and empagliflozin as indicated in all HFrEF patients, irrespective of their diabetic status, to reduce the risk of heart failure-related death or hospitalization (class I level of recommendation A) [46,50].

Encouraged by the positive results in the HFrEF field and taking into account the lack of available medications with prognostic effects in HFpEF, the idea of investigating the efficacy of these medications in this prevalent HF phenotype has emerged. And initial evidence emerged from the SOLOIST-WHF trial, which evaluated the effects of sotagliflozin, the dual SGLT1/SGLT2 inhibitor, initiated soon after an episode of decompensation of heart failure; sotagliflozin proved a lower risk of a primary composite end-point formed by cardiovascular death or hospitalizations and urgent visits for heart failure (HR, 0.67; 95% confidence interval [CI], 0.52 to 0.85; P<0.001). The result, suggesting a potential effect of SGLT2i in HFpEF, was that the risk reduction of the primary end-point was consistent across the entire spectrum of ejection fraction [51].

Empagliflozin gained evidence for HFpEF and HFmrEF attributable to the results of the EMPEROR-Preserved trial (which included patients with an ejection fraction above 40%). Empagliflozin 10 mg once daily reduced a composite end-point of worsening heart failure or cardiovascular death (hazard ratio, 0.79; 95% confidence interval [CI], 0.69 to 0.90; P<0.001), a result driven by a significant reduction in the risk of worsening heart failure (with no difference in death from cardiovascular causes) [52]. Likewise, in the DELIVER trial (heart failure patients with an ejection fraction above 40%), dapagliflozin 10 mg od reduced the events of a similar primary composite end-point (hazard ratio, 0.82; 95% confidence interval [CI], 0.73 to 0.92; P<0.001). Once again, this effect is attributable to the reduction of the worsening heart failure events, without significant effects on cardiovascular mortality [53]. As a result, clinical guidelines have been harmonized and currently recommend empagliflozin and dapagliflozin (unique dose of 10 mg per day) in HFpEF and HFmrEF for the reduction of the risk of HF hospitalization or cardiovascular death (class I recommendation in European guidelines, class IIa recommendation in American guidelines) [50,54].

Important evidence for using SGLT2i in heart failure derives from the EMPULSE trial, in which empagliflozin was initiated in hospitalized acute heart failure after stabilization, regardless of ejection fraction or diabetes status. The primary analysis was a win ratio, being a composite of death, heart failure events, time to first heart failure event, and modifications in KCCQ. Empagliflozin proved a better win ratio, with a statistically significant result (win ratio 1.36, 95% CI 1.09-1.68, p=0.0054), with consistent results across the prespecified subgroups [55]. Besides this combination of prognostic and symptomatic benefits, empagliflozin also proved significant results on various indices of decongestion, suggesting that early initiation of empagliflozin in hospitalized acute heart failure patients also has the potential to contribute to an early and sustained decongestion [56].

Regarding the benefits of SGLT2 inhibitors in another acute setting—this time early after myocardial infarction—a recently published meta-analysis concluded that early administration of SGLT2i post-myocardial infarction may be beneficial by reducing the risk of recurrent major adverse cardiovascular events (MACE) or hospitalization for heart failure. However, this meta-analysis did not demonstrate a significant reduction in mortality among these patients [57].

Similar to GLP-1RA, SGLT2i is also an effective medication in chronic kidney disease. Based on findings from early studies on cardiovascular safety, specific trials have been designed to directly assess the potential beneficial effects of SGLT2i in CKD. 4 trials, CREDENCE (for canagliflozin), DAPA-CKD (for dapagliflozin), SCORED (for sotagliflozin), and EMPA-KIDNEY (for empagliflozin) proved that SGLT2i slow the progression of CKD. Whereas for canagliflozin and sotagliflozin, the effects were proven only in T2DM populations, in contrast, for empagliflozin and dapagliflozin, the effects were irrespective of the diabetic status, similar to HF trials. It is important to mention that the recommendation is to initiate dapagliflozin at an eGFR of at least 25 ml/min/1.73m^2 and empagliflozin at an eGFR of at least 20 ml/min/1.73m^2, but the administration may continue even if the renal function further deteriorates (this indication derives from the design of the studies and the characteristics of the included patients) [58].

Table 2: Major CVOTs of SGLT2i [42]

	Type 2 diabetes mellitus	**Heart failure**	**Chronic kidney disease**
Proved effects	In high-risk cardiovascular patients, it reduces the risk of major adverse cardiac events or cardiovascular death. (Besides improved glycemic control and weight loss)	Reduce the risk of heart failure-related death or hospitalization (across the entire ejection fraction spectrum) Improves decongestion in stabilized acute heart failure (empagliflozin)	Mitigate the progressive reduction of eGFR and lower the risk of renal or cardiovascular-related death
Drugs approved	Canagliflozin, Dapagliflozin, Empagliflozin, Ertugliflozin	Dapagliflozin, empagliflozin	Canagliflozin, Dapagliflozin, Empagliflozin
Guideline recommendations	Recommended as first-line add-on therapy to metformin, especially in cardiovascular high-risk, heart failure, or CKD patients	Class I recommendation in HFrEF Class I recommendation in ESC guidelines, class IIa recommendation in ACC/AHA guidelines for HFpEF	T2DM and CKD with eGFR>20 ml/min/1.73m^2 ACR>200 mg/g (and eGFR>20 ml/min/1.73m^2) ACR<200 mg/g with eGFR 20-45 ml/min/1.73m^2 CKD + heart failure

MINERALOCORTICOID RECEPTOR ANTAGONISTS (MRAs)

It is known that overactivation of the renin-angiotensin-aldosterone system and aldosterone receptors (mineralocorticoid receptors, MR) in particular, has effects beyond salt and water retention and hypertension. MR overactivation is capable of inducing inflammation and fibrosis in various organs, being involved in CKD and CV disease progression, situations in which RAAS is overly activated and aldosterone is in excess [73]. As far as metabolic derangement is involved, diabetes mellitus also induces a state of overactivation of MRs, and in obese patients there was observed a significant aldosterone production from adipose tissue was observed [74,75].

The deleterious effects of excess aldosterone are facilitated by the widespread expression of mineralocorticoid receptors throughout the body, as they are present not only in the kidneys but also in the heart, blood vessels, gastrointestinal tract, adipose tissue, and central nervous system [73].

The first therapeutic options to block MRs were the steroidal agents spironolactone and eplerenone, respectively.

The first results for these agents came from RCTs, which tested them in HFrEF, a common entity in advanced stages of cardio-renal-metabolic syndrome. In RALES trial, conducted in 1999, spironolactone reduced all-cause mortality by 30% (RR, 0.70; 95% CI, 0.60 to 0.82; P<0.001) and the risk of heart failure hospitalization by 35% (RR 0.65; 95% CI, 0.54 to 0.77; P<0.001), besides observed benefits on improvement regarding the symptoms of heart failure [76]. Eplerenone gained evidence from the EMPHASIS-HF trial, which proved a significant reduction of the primary composite endpoint of CV death or heart failure hospitalization (HR, 0.63; 95% CI, 0.54 to 0.74; P<0.001) [77]. Further trials provided evidence for steroidal MRAs, namely eplerenone, early after myocardial infarction. EPHESUS and REMINDER trials found that eplerenone, early initiated after MI, in patients with clinical signs and symptoms of heart failure and an ejection fraction of less than 40% could reduce all-cause mortality, length of hospitalization due to heart failure, ventricular arrhythmias, or the risk for deterioration of ejection fraction [78,79]. The beneficial effects of MR blockade in HFrEF and after myocardial infarction emphasize the important effects of aldosterone in cardiac adverse remodelling.

Regarding the HFmrEF and HFpEF, the available results are not as solid as in HFrEF. In the TOPCAT trial, 3,445 patients with symptomatic heart failure and a left ventricular ejection fraction of ≥45% were randomized to receive either spironolactone or placebo. Although the study narrowly failed to meet its primary composite endpoint (including cardiovascular death, aborted cardiac arrest, and hospitalization for heart failure), its results generated considerable debate [80]. The difference between a significant HR in American cohort (HR, 0.82; 95% CI, 0.69-0.98; p = 0.026) and a non-significant HR in Russian and Georgian cohort (HR, 1.10; 95% CI, 0.79-1.51; interaction p = 0.12) has led to speculation that the apparent neutral results of the TOPCAT trial may be due to issues with enrollment and drug adherence in the Eastern European cohort [81]. Based on the significant results on American cohort, there is a 2b recommendation in ACC/AHA guidelines on heart failure for steroidal MRA use in HFpEF and HFmrEF [50].

Hypertension in general and resistant hypertension in particular are common entities in chronic kidney patients or in obese, insulin-intolerant, or diabetic patients. Resistant hypertension is associated with a poor prognosis, causing target organ damage. The PATHWAY-2 RCT established spironolactone as a first-line agent in resistant hypertension, on top of maximum tolerated doses of ACEI/ARB, calcium-channel blocker, and thiazide diuretic [82].

The main limitation of steroidal MRAs' use is the risk of hyperkalemia, a risk observed since the early trials and considered relatively significant, particularly in a population with chronic kidney disease. A meta-analysis that included the landmark RCTs of steroidal MRAs proved that the risk of hyperkalemia and the benefits are inversely proportional to the eGFR (with unclear benefits compared to high risk of hyperkalemia in patients with an eGFR<30 ml/min/1.73m^2) [83].

Gynecomastia and breast pain are other well-known and relatively frequent adverse effects of spironolactone (with a 10% to 1% ratio observed in the RALES trial) [73].

There is a limitation in the steroidal MRAs' potential for broader cardiorenal protection, given the fact that their widespread use is limited by hormonal adverse effects or, in advanced CKD, by a significant risk of hyperkalemia. Moreover, data regarding the direct effects of steroidal MRAs on slowing CKD are unconvincing. There is a meta-analysis that proposes some benefits on intermediate endpoints such as albuminuria or eGFR slope, albeit at the cost of significant risk of hyperkalemia, worsening renal function, or gynecomastia [84].

The novel class of non-steroidal mineralocorticoid receptor antagonists (nsMRAs) has emerged in an effort to overcome these limitations while preserving the beneficial effects of the steroidal MRAs.

Finerenone is the most prominent agent of this pharmacological class, with several advantages over its steroidal counterparts: a comparable potency of MR inhibition but with a much higher selectivity, virtually no sexual side-effects, a more balanced tissue distribution between kidneys and the heart (in comparison with sMRA which are more concentrated at the renal level) and a shorter plasma half-time, which might contribute to a lower risk of hyperkalemia [85,86].

The first RCTs investigating finerenone were FIDELIO-DKD and FIGARO-DKD. FIDELIO-DKD primarily enrolled diabetic patients suffering from advanced CKD with prominent albuminuria, and there was a prespecified primary composite kidney endpoint. FIGARO-DKD enrolled diabetic patients with moderate albuminuria associated with a wider spectrum of CKD and stated a primary composite cardiovascular endpoint [85]. The results from these 2 RCTs and from their pooled analysis (FIDELITY) form the basis for the KDIGO guideline recommendation of finerenone in CKD: in patients with diabetic nephropathy, with an eGFR>25 ml/min/1.73 m^2 and with an albuminuria >30 mg/g, despite a maximum dose of ACEI/ARB [72]. Apart from reducing the kidney disease progression, finerenone reduced cardiovascular risk (HR 0.86, 95% CI: 0.78-0.95) and the risk of heart failure hospitalization (HR 0.78, 95% CI 0.66-0.92) in diabetic CKD patients [86].

The latter FINEARTS-HF trial provides the first quality results for MRAs (particularly nsMRA, finerenone) in HF with EF above 40%. In this RCT, finerenone reduced the risk of a primary composite endpoint formed by worsening heart failure events and cardiovascular death with 16% (rate ratio, 0.84; 95% confidence interval [CI], 0.74 to 0.95; P=0.007), driven by a significant reduction in worsening heart failure events, similar to SGLT2i results in the same patient population [87]. Compared to the previous ones, FINEHEARTS was a revolutionary trial also by the population included, with approximately 60% not having CKD or diabetes, suggesting that there may be important direct effects on the heart [88].

The recent FINE-HEART meta-analysis allows for the formulation of global conclusions regarding finerenone as far as cardiovascular and renal outcomes are concerned. This meta-analysis included the three RCTs, FIDELIO-DKD, FIGARO-DKD, and FINEARTS-HF, encompassing a total of 18991 patients. 12.1% of the included patients concurrently had HF, CKD, and diabetes, the main conditions encompassed in the CKM syndrome. The results indicate that finerenone reduces the risk of heart failure hospitalization (HR: 0.83; 95% CI: 0.75-0.92; $P < 0.001$) and of a composite kidney outcome, thus delaying CKD progression (HR: 0.80; 95% CI: 0.72-0.90; $P < 0.001$). Although not succeeding in proving risk reductions in cardiovascular death (HR 0.89; 95% CI: 0.78-1.01; $P = 0.076$), finerenone seems to reduce the risk of all-cause death (HR: 0.91; 95% CI: 0.84-0.99; $P = 0.027$) [88].

Currently, the sole recommendation for finerenone within cardiology guidelines is the class IA recommendation in the 2023 ESC Guidelines for the management of cardiovascular disease in patients with diabetes, in patients with type 2 DM and CKD (UACR>300 mg/g or eGFR 25-60 ml/min/1.73m^2 and UACR>30 mg/g), in addition to ACE-I or ARB, to reduce the risk of cardiovascular events or kidney failure [26].

This recommendation, similar to those related to SGLT2i or GLP-1RA, empowers all medical doctors involved in the management of CKM syndrome to take proactive measures aimed at improving the prognosis of these patients. It remains to be seen what future heart failure guidelines will unveil regarding nsMRA indications, probably related to future trials that may investigate the effects of finerenone in this population.

CONCLUSION

Management of cardiovascular disease within the cardiorenal metabolic (CKM) syndrome requires a comprehensive, individualized approach, guided by cardiovascular risk stratification. While lifestyle interventions remain foundational, pharmacologic therapy plays a pivotal role in improving prognosis and quality of life.

Standard treatments such as RAAS blockade—with ACE inhibitors, ARBs, and steroidal MRAs—form the therapeutic backbone. However, recent advances support the early initiation of novel agents with proven benefits across all three CKM components.

GLP-1 receptor agonists and dual GLP-1/GIP agonists (e.g., tirzepatide) not only promote glycemic control and weight reduction but also lower the risk of major adverse cardiovascular events and may preserve renal function. SGLT2 inhibitors have demonstrated robust prognostic benefits in heart failure—regardless of ejection fraction—and chronic kidney disease, independent of glycemic status. Finerenone, a non-steroidal mineralocorticoid receptor antagonist, is recommended in diabetic kidney disease with albuminuria and shows emerging evidence of efficacy in HFpEF and HFmrEF, although formal guideline recommendations are still pending.

Optimizing therapeutic strategies with both established and novel agents is essential for altering the course of heart disease in CKM syndrome and addressing its complex, multisystem pathophysiology.

CLINICAL PRACTICE

Endoscopic eradication of nodular gastric vascular antral ectasia by using band ligation after argon plasma coagulation

Sandica Bucurica[1,2], Mihaela Ailenei[1], Mariana Jinga[1,2], Florentina Ioniță Radu[1,3]

Abstract: *Gastric antral vascular ectasia (GAVE) is an important cause of gastro-intestinal bleeding. The most common clinical presentation of GAVE is chronic occult bleeding that leads to symptomatic iron deficiency anemia, but some cases could present with acute massive bleeding. Frequently, patients are dependent by iron suplimentation, or in severe cases even blood transfusions. Endoscopic therapy is frequently necessary in acute or chronic blood loss. Over the past several years, treatment for GAVE has continued to evolve as the number of available effective therapeutic interventions has increased. These included: YAG laser, argon plasma coagulation (APC), endoscopic band ligation, cryotherapy and surgical anterectomy. Argon plasma coagulation is the most commonly used technique, but has been associated with several complications like sepsis, post-APC bleeding, gastric outlet obstruction and increased incidence of hyperplastic polyps. Endoscopic band ligation (EBL), a mechanical procedure, has been reported in the past years as an effective salvage therapy for GAVE that is refractory to other approaches, or even as the first line treatment. We present a case of nodular GAVE treated succesfully with endoscopic band ligation after unsuccesufull sessions with argon plasma coagulation.*

Keywords: *gastric antral vascular ectasia, endoscopic band ligation, Argon plasma coagulation, gastro-intestinal bleeding*

INTRODUCTION

Gastric antral vascular ectasia (GAVE) or "watermelon stomach" is a relatively rare cause of gastrointestinal (GI) bleeding that mainly affects women aged 70 years and older. The incidence is estimated to be aproximately 4% of upper GI bleeding [1]. The term "watermelon stomach" is derived from the characteristic endoscopic appearance of longitudinal rows of flat, reddish stripes radiating from the pylorus into the antrum that resemble the stripes on a watermelon [2].

It usually presents as occult bleeding with chronic iron deficiency anemia. Even though GAVE was first diagnosed about six decades ago, its etiopathogenesis has not been fully established yet, with many hypotheses proposed such as mechanical stress, hormonal factors, and autoimmune factors. It is associated with liver cirrhosis, autoimmune disease, connective tissue disorders and collagen vascular disorders (eg, systemic sclerosis, Sjogren syndrome), chronic renal failure, bone marrow transplantation, acute myeloid leukemia and heart disease.

Frequently GAVE patients have chronic GI bleeding, but sometimes it can cause severe acute life-threatening bleeding especially in elderly with multiple chronic medical illnesses [2].

GAVE is typically located in the gastric antrum; however, it may be also found rarely in other areas of the GI tract, including cardia, duodenum, jejunum, and rectum. The

involvement of the proximal part of the stomach is very rare and commonly located within a diaphragmatic hernia.

At endoscopy, GAVE may appear as 2 types. First type is the diffuse punctuate lesions in the antrum typically seen in male patients with cirrhosis and commonly accompanied by acute bleeding. Second one is the red lesions organized in stripes radially departing from the pylorus, known as “watermelon stomach”, mostly common in females with connective tissue diseases and usually present with occult bleeding [1].

Histopathologically, GAVE is characterized by vascular ectasia, spindle cell proliferation, and fibrohyalinosis. Immunohistochemical staining for CD61, a platelet marker, further confirms a diagnosis of GAVE [3].

Over the years, treatment for gastric antral vascular ectasia (GAVE) has continued to evolve and the number of available treatments has continued to increase, including surgical, medical and endoscopic therapies

Medical therapy has not clearly shown satisfactory results. Multiple drugs, such as hormonal (estrogen-progesterone) therapy, steroids, octreotide and tranexamic acid, have been tried to control GAVE-related bleeding. After all, no one has clearly shown satisfactory results in order to consider medical therapy as a valid alternative to an invasive approach.

Endoscopic therapies have rapidly become the first line therapy with argon plasma coagulation (APC) as the most common used method and more recently with radiofrequency ablation system (RFA) using Halo90 catheter and endoscopic band ligation (EBL). Both of them have been shown to be safe and effective for GAVE treatment. The latter two have been utilized in treatment of severe, diffuse, APC refractory GAVE. The clinical outcomes of ablative therapy such as APC treatment or HALO90 system were reported as 80%-100% success rate.

Other therapies include Nd:YAG (neodymium:yttrium-aluminum-garnet) laser coagulation, but with a higher risk of perforation given the deeper thermal effect. Endoscopic sclerotherapy, heater probe, cryotherapy have also been described in the literature. For unresponsive cases to endoscopic therapy, surgery with antrectomy can be considered but carries a high surgical risk, especially in the cirrhotic patients.

APC is most commonly used method, but has been associated with sepsis, post-APC bleeding, gastric outlet obstruction and increased incidence of hyperplastic polyps’ formation. It is needed multiple sessions of APC to reduce bleeding episodes and/or decrease transfusion dependence. APC has been found to be equally effective in the treatment of GAVE and is superior to ND:YAG laser in cost, convenience and complication rates(4).

The non-ablative treatment options is the endoscopic band ligation. EBL was firstly reported as the treatment for refractory GAVE in the patients who failed other treatment modalities such as APC or hormonal therapy by Sinha et al. [5]

Endoscopic band ligation has been reported as an alternative effective endoscopic therapy and the rate of complication is low in comparison with those reported for APC in retrospective studies [6].

A case series of 9 patients reported by Wells et al also showed superiority of EBL over endoscopic thermal therapy, which were APC and bipolar thermal probe therapy, for the rate of re-bleeding, duration of hospitalization and post procedure transfusion. The complications reported for this procedure were very small. Band ligation was prefered as the first line treatment regarding of the extensive involvement of the lesion in the patients. According to the result of the treatment mentioned above, endoscopic band ligation could be considered as first line treatment options for the GAVE patients especially for extensive area of involvement. [7]

A recent prospective study showed endoscopic improvement with the use of endoscopic band ligation in 91% of the patients, with a significant improvement in the hemoglobin and ferritin levels. Band ligation in GAVE has been associated with transient abdominal pain in a minority of the patients, but no major complications have been reported in the literature. [9]

Some studies suggest that the number of sessions required for GAVE eradication is inferior when using EBL compared to APC, resulting in inferior health care costs. However, randomized controlled trials are lacking to determine whether EBL is more cost effective than APC as the primary endoscopic therapy for GAVE. [9, 10]

Although initial reports of these endoscopic modalities are encouraging, well-performed, larger, prospective studies are needed before providing any definitive conclusion.

CASE PRESENTATION

Clinical data

We present a case of a 57-year-old female, diabetic with multiple microvascular complications – diabetic polineuropathy and chronic renal disease, hypertensive, with moderate hypochromic microcytic anaemia and a positive fecal occult blood test (FOBT), already in treatment with iron therapy who presented for abdominal pain, fatigability, phisical astenia and arthralgias. She denied no change in weight, bowel pattern, or stool color. The physical examination revealed paleness of the skin and mucosa and otherwise unremarkable.

Laboratory data

Labs indicates a moderate hypochromic microcytic anaemia (hemoglobine level – 9.4 g/dL, mean corpuscular volume – 70.2 fL, hematocrit – 31.1%, mean corpuscular hemoglobin – 21.2 picog and sideremia – 26 microg/L.

Endoscopy

Superior digestive endoscopy showed hypertrofic gastric antral vascular ectasia with mucosal eryhema, friability and visible small vessels extending radially in linear rows throughout the antrum and a duodeno-gastric reflux. She underwent serial argon plasma coagulation treatments and a second gastroscopy was performed next day which showed post argon plasma coagulation ulcers which were biopsied.

Histopathology data

Ulcer post argon plasma coagulation biopsy performed showed modifications of chronic inactive gastritis, but GAVE was not confirmed on biopsy.

Evolution

After two months and with iron therapy, the hemoglobin level was normalised (12.7 g/dL) with low mean corpuscular volume and mean corpuscular hemoglobin. At the endoscopic examination the macroscopic appearance persisted with multiple friable hypertrofic and nodular antral vascular ectasia and duodeno-gastric reflux.

At 3 months follow-up, hemoglobin level mantained in the normal interval (13.5 g/dL), but the endoscopic appearing was worst, with larger, friable, with edema and hypertrofic gastric atral vascular ectasia (Figure 1). We decided to apply 6 elastic bands on the biggest lesions with success (Figure 2). No complications of the procedure were reported, and the patient was discharged after 24h.

Figure 1: Endoscopic appearance from the index endoscopy, demonstrating multiple erythematous friable antral hypertrophic and nodular lesions, representing nodular gastric antral vascular ectasia (GAVE)

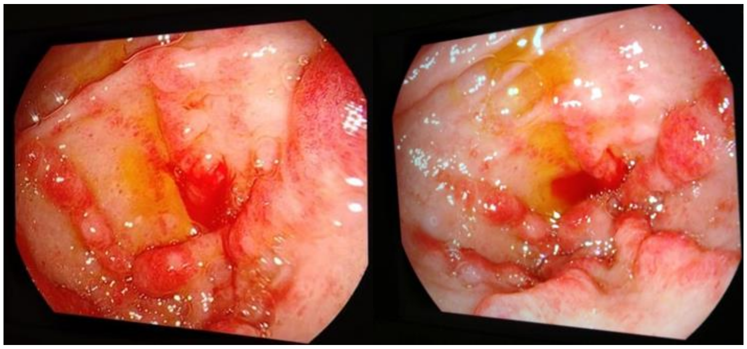

Figure 2: Endoscopic image from the band ligation of GAVE

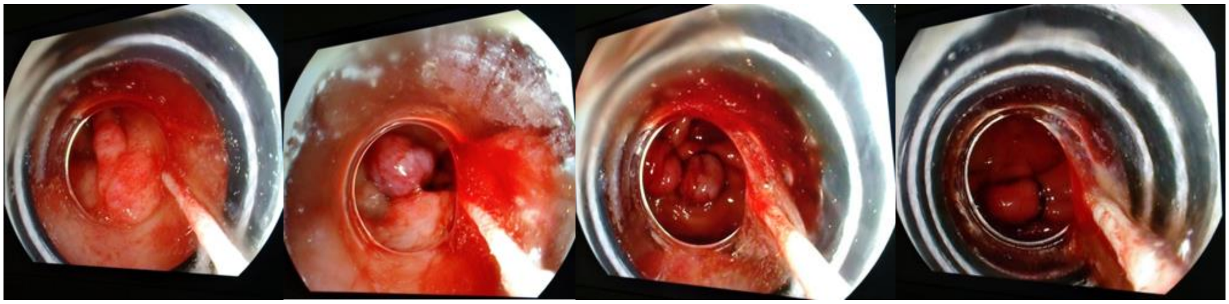

Two months later, hemoglobin level was stable (13.4g/dL). The upper endoscopy revelead small hyperemic antral circumferential disposed lesions with no signs of bleeding and no hypertrophy, with almost complete eradication of GAVE (Figure 3).

DISCUSSION

GAVE is a poorly understood entity, of unknown etiology, and an increasingly identifiable cause of chronic iron deficiency anemia. The pharmacological management of

GAVE had only poor results, so the mainstay of GAVE management remains endoscopic therapy.

Figure 3. Endoscopic appearance 2 months after endoscopic band ligation

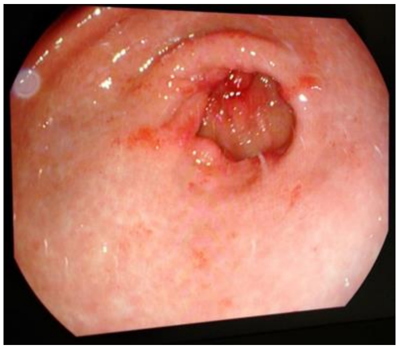

Figure 4. Suggested flow chart for treatment algorithm [14]. GAVE: Gastric antral vascular ectasia; APC: Argon plasma coagulation; RFA: Radiofrequency ablation; EBL: Endoscopic band ligation.

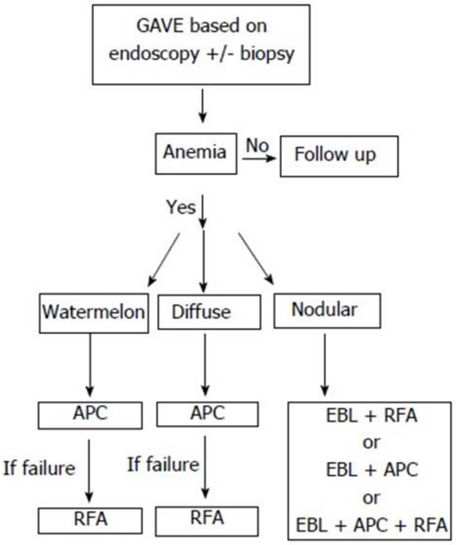

APC is a modality of non-contact electrocoagulation that applies high-frequency energy into tissue to cause thermal effects, which has been used successfully to treat GAVE with an effective transient response, but primary failure rates of therapy of up to 14% have been reported. Some authors suggest that this endoscopic method is insufficient in order to achieve medium and long-term treatment success, as it has been associated with a high recurrence rate (40–100%) [11].

In addition, APC might have complications, such as sepsis, pyloric stenosis and gastric outlet obstruction syndrome, in 20–33% of the patients [12].

EBL has been reported to be a relatively easy technique for GAVE therapy, has been shown to be safe and effective with lower complication rates in comparison with APC. Both Sato et al. [6] in 2012 and Prachayakul er al. [13] in 2013 conclude that EBL may be useful in the treatment of GAVE, to avoid the high recurrence rate after APC.

In this case, the patient was initially treated with APC after being diagnosed with GAVE as the cause of iron deficiency anemia, but this strategy was not successful. APC treatment might not be effective in some cases, especially in the case of hypertrofic and nodular type of GAVE, and this could be explained by the limited depth of thermal injury.

Since the histological changes are present in the mucosa and submucosal layer, EBL may be more effective for GAVE because of its ability to obliterate the submucosal vascular plexus like for esophageal varices. In this patient, the presence of extensive areas of the antrum affected with a high-density of both mucosal and submucosal vascular malformations is a likely explanation for the primary failure of the APC treatment.

It is becoming apparent that patients with severe, diffuse or refractory disease require multimodal therapy. Our case not only shows that, but also that patients specifically with nodular variant GAVE require and respond well to multimodal therapy.

Abstract: Introduction: Non-melanoma skin cancers (NMSC) represent a significant global public health burden, particularly in high-income countries. The increasing incidence of head and neck NMSC contributes to rising morbidity and necessitates multi-disciplinary management. Objectives: This study aims to evaluate the incidence, demographic distribution, histological subtypes, and seasonal variation of NMSC over a five-year period at a tertiary center in Romania. Materials and Methods: A retrospective observational study was conducted from January 2020 to December 2024, including 180 patients diagnosed and treated for malignant skin lesions. Data were extracted from clinical and histopathological records. Chi-square tests assessed seasonal distribution, and Mann-Whitney U tests compared lesion depth and surface area between demographic groups. Results: A total of 388 malignant lesions were recorded. Basal cell carcinoma (BCC) was the most common subtype (n = 168), followed by squamous cell carcinoma (SCC) (n = 25). Most patients resided in urban areas, particularly Bucharest. Males presented with significantly deeper lesions (mean: 1.5 mm) compared to females (mean: 1.25 mm; p = 0.009). Seasonal analysis revealed a significant variation in incidence, with the lowest number of cases in spring ($\chi^2 = 10.31$, $p = 0.016$). Conclusion: The incidence of malignant skin lesions increased from 2020 to 2023, followed by a decline in 2024. Seasonal and sex-related differences were observed, with the face being the most frequent site of involvement. While the sex distribution was relatively balanced, males exhibited significantly greater lesion depths compared to females.

INTRODUCTION

Cutaneous malignancies accounts for most cancers across the world and they are primarily divided into melanoma (MSC) and non-melanoma (NMSC) skin cancers [1]. According to the Globocan (Global Cancer Observatory) 2022 data, non-melanoma skin cancer ranks as the fifth most commonly diagnosed cancer worldwide, with over 1.2 million new cases reported [2]. However, despite its high incidence, NMSC ranks only 22nd in terms of cancer-related mortality, highlighting the generally favorable prognosis of NMSC compared to other malignancies [2].

The incidence of head and neck MSC and NMSC is rising all over the world and can be the source of significant morbidity and mortality [3]. The necessity of a multidisciplinary team that includes dermatology, plastic and reconstructive surgery, medical and radiation oncology remains a financial problem in many countries, due to the comprehensive care that needs to be provided for patients with head and

neck cutaneous malignancies [3,4].

The vast majority of non-melanoma skin cancers include basal cell carcinoma (BCC), followed by squamous cell carcinoma (SCC), both showing a rapidly increasing trend in their incidence in the last years and a significant health burden in many countries [5,6]. Although the exact global incidence of these two is unknown, an overview of the last years carried out by World Health Organization concluded that BCC comprises about 80% of all NMSC, while SCC comprise about 20%, with a BCC to SCC ratio ranging from 2 to 4:1 [5,6]. While this is a classic agreed ratio, the recent studies suggest a possible changing in the pattern due to aging of the population, with equal numbers of SCC and BCC being treated in the future [6,7].

Multiple etiological risk factors related to the individual or the environment were studied for understanding the cause of NMSC, but the main driving carcinogen remains ultraviolet radiation (UVR) [5,6]. This explains why over 80% of these malignancies occur on the sun exposed skin of the head and neck (followed by the hands and forearms), with higher prevalence of BCCs in the nasal area, while SCCs are preferentially located on the auricle [5,8,9]. UVR are responsible for the induced dinucleotide mutations at pyrimidine bases, exhibiting strong transcription strand bias and also showing a high mutational burden with the mutant genes varying between BCCs and SCCs [6].

Although its mortality is low and it rarely results in metastatic disease, BCCs can cause significant health burden through his great morbidity, generated by the destructive local spread [9]. These tumors are slow growing but can, however, develop large, causing locally tissular destruction and spreading into vital structures such as the central nervous system or important blood vessels [10]. Traditionally, the five most commonly accepted histological subtypes of BCC, described by Lang and Maize, include superficial, nodular, micronodular, infiltrative and morpheaform or sclerosing BCC [10,11]. Of note, a particular form of BCC, called the basosquamous cell carcinoma (BSCC) or the metatypical BCC, may arguably be a SCC subtype, as it shows both basal cell and squamous cell cancer differentiation in a continuous fashion [10,11]. The metatypical BCC, together with morpheiform and infiltrative BCC belong to the aggressive-growth subsets, while the others are considered indolent-growth variants [11]. Regarding their epidemiology, in one large retrospective study on 1039 consecutive cases of BCC, the histological analysis demonstrated 21% were nodular, 17% superficial, 15% micronodular, 7% infiltrative and just 1% morpheic [12].

In contrast with basal cell carcinoma, the squamous cell carcinoma has metastatic potential, and when present, the general prognosis is rather poor due to the mortality associated with regional and nodal metastases [9]. It is the most common skin cancer after BCC and generally has a good prognosis, the overall metastasis rate varying from 1% to 4% [13]. There are several risk factors attributed with the regional metastatic potential, like a poor differentiation, a perineural invasion, the presence of recurrency, a depth of invasion greater than 6 mm or a size bigger than 2 cm [14]. The SCC typically develop in a progressive manner, beginning with premalignant lesion -actinic keratosis (AK)-to in situ SCC (Bowen's disease) and eventually to invasive squamous cell carcinoma [13]. Usually, only a small proportion of the precursors develop into invasive cutaneous SCC [13,15]. Despite that, the high mortality of the metastatic variant and the high frequency of SCC in general remain of great concern and represent a financial burden for the health care services, as it needs a close clinical surveillance for many years [15].

Unlike the BCC variants, where the biological behaviors show little significant difference, there are a wide histopathological subtype of SCCs which demonstrates not just microscopic differences, but also a very diverse clinical behaviors [16]. There are several histologic subtypes of SCC and each of them carry an important prognostic significance [16,17]. The generic type (the simplex or conventional) has the greatest risk of metastasis, followed by lobular (acantholytic), Bowenoid, spindle (pleomorphic)-all three with a similar risk- and the last, verrucous carcinomas, has the most favorable prognosis [16,17]. Another predicting cancer behavior in cutaneous squamous cell carcinoma are the histopathologic parameters, which stage tumors into four categories primary based on their nuclear pleomorphism [17]. According to Broder, the tumors can be well-differentiated (less than 25% undifferentiated cells), moderately- well differentiated (less than 50% undifferentiated), poor differentiated (less than 75% undifferentiated) and anaplastic or pleomorphic (more than 75% undifferentiated) [17].

Nevertheless, the spectrum of head and neck cutaneous malignancies ranges from fairly well-behaved tumors (most of the BCCs) to potentially very aggressive cancers with high metastatic rate (usually melanoma, but also some histologic types of SCC) [3]. Their increasing incidence, the necessity of a multidisciplinary team and the need of a well-developed early screening evenly distributed among countries and regions, make the topic current and highly important in the present context.

The aim of this paper is to present the incidence of non-melanoma skin cancers of the head and neck in a single tertiary center in a retrospective study, from 2020 to 2024. Also, we'll describe the correlation between malignancies and gender, age, type of cancer, and its dimensions, together with trends in their frequency. Understanding temporal trends and potential fluctuations in incidence is essential for effective healthcare planning and resource allocation. Seasonal patterns in skin cancer diagnoses suggest that environmental factors, such as ultraviolet exposure, may influence disease occurrence and warrant further investigation. Additionally, variations in lesion characteristics between different demographic groups, including sex and geographic location, highlight the importance of exploring underlying biological, behavioral, and healthcare access factors. Investigating these aspects can contribute to improved prevention strategies, early detection, and tailored treatment approaches for skin cancer patients.

MATERIALS AND METHODS

A retrospective observational study was conducted on a database of patients diagnosed and treated for malignant skin tumors at a tertiary care center in Romania between January 2020 and December 2024. Due to the COVID-19 pandemic, there is a notable gap in data collection between April 2020 and June 2021, during which clinical activity was significantly reduced. The goal was to assess demographic distribution, histological types, anatomical localization, and treatment patterns of skin cancer patients in Romania in the last 5 years. Data were extracted from the institution's electronic medical records and physical registries, curated by the dermatology department.

The patients were selected using the following inclusion criteria: Patients with a clinical diagnosis of a skin lesion suggestive of malignancy; Hospital admission (i.e., full inpatient hospitalization, not outpatient consultation or day-case admissions); Histopathological confirmation of a malignant skin tumor.

Exclusion criteria consists of: Benign skin lesions and suspected malignancies for which no biopsy was performed (e.g., due to patient refusal or other contraindications).

Following the application of the inclusion criteria, a total of 388 malignant non-melanoma skin lesions were identified across 180 patients. While most patients presented with an average of approximately 2–3 lesions, a small subset exhibited over 10 malignant lesions each. Although not all lesions underwent histopathological confirmation, those that were not biopsied shared highly similar macroscopic features with confirmed cases, allowing for a reliable clinical diagnosis based on visual assessment.

The dataset includes both male and female patients residing in Bucharest as well as in 19 other counties across Romania. All patients sought medical evaluation and treatment at the tertiary facility. Of the 180 eligible patients, 125 (69.4%) originated from urban areas, while 55 (30.6%) were from rural settings. Sex distribution was relatively balanced, with 52% of the cohort being female and 48% male. Patient ages ranged from 35 to 93 years, with a median age of 69 years for females and 71 years for males.

The standard clinical pathway involved an initial dermatologic evaluation, during which a provisional diagnosis was made based on the morphological characteristics of the lesion. Patients then underwent a biopsy for histopathological confirmation. Upon receiving the diagnostic result, patients returned for definitive treatment, which typically consisted of complete surgical excision or electrocauterization, depending on the lesion's type, size, and location.

The following variables were systematically collected for each patient: demographic information (including age, sex, and place of residence); clinical characteristics (lesion location, provisional clinical diagnosis, year and month of diagnosis); histopathological data (tumor type and size); and treatment details, specifically the definitive procedure performed—either surgical excision or electrocauterization—as well as the occurrence of recurrence or the need for re-excision.

All tissue specimens were processed and analyzed by board-certified pathologists within the same department, using standard hematoxylin-eosin (H&E) staining tech-niques.

Data base was created using Microsoft Excel 2019. Statistical analysis was per-formed using JASP 0.19.3 program. Statistical analyses included Chi-square tests to as-sess seasonal distribution differences and Mann-Whitney U tests to compare lesion depth and surface area between demographic subgroups.

RESULTS

When analyzing the annual incidence of malignant skin lesions, a progressive in-crease was observed over the first four years of the study period: 18 cases in 2020, 25 in 2021, 40 in 2022, and a peak of 63 cases in 2023. This upward trend was followed by a decline in 2024, with 34 cases recorded (Fig. 1). A linear regression analysis revealed an average annual increase of approximately 7 cases (slope = 7), with a coefficient of determination (R^2) of 0.64, suggesting a moderate correlation between time and case number. However, the trend did not reach statistical significance ($p = 0.244$), likely due to the limited number of years analyzed and the variability introduced by external factors such as the COVID-19 pandemic in 2020–2021, the post-pandemic rebound in 2023, and the subsequent decrease observed in 2024.

The average hospitalization duration remained relatively stable over the past five years, starting at 4.2 days in 2020, slightly increasing to 4.5 days in 2021, then gradually decreasing to 4.3 days in 2022, and further declining to 4.1 days in both 2023 and 2024 (Fig. 2). The longest hospital stay was recorded in 2020, lasting 19 days, while the shortest stays of 2 days were observed in 2023 and 2024.

Figure 1.The trend line of malignant skin lesions

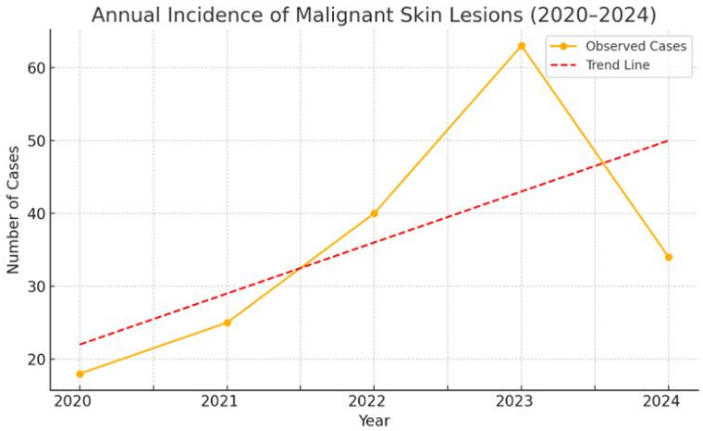

Figure 2. Evolution of the average hospitalization days (2020-2024)

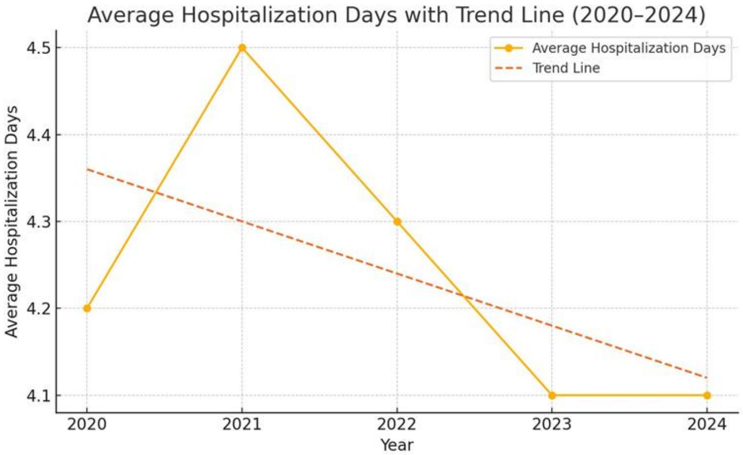

Of the 180 patients, 95 were residents of Bucharest, with the highest concentration coming from Sector 3 (n = 35) and Sector 4 (n = 32). Among patients from outside the capital, the neighboring counties of Ilfov (n = 16) and Giurgiu (n = 14) were the most represented.

When assessing seasonal distribution over the five-year period, the lowest incidence of diagnosed malignancies was observed in spring, with only 27 cases recorded. The other seasons showed relatively similar frequencies, with 47 cases in summer, 55 in autumn, and 51 in winter (Table 1, Fig. 3). In order to determine whether there is a significand difference between the observed frequencies and expected frequencies, we have applied the Chi-squeare test (χ^2). The test revealed a statistically significant difference in the seasonal distribution of skin cancer diagnoses ($\chi^2 = 10.31$, $p = 0.016$).

Table 1. Presentation period by month, year and season

Presentation period	**2020**	**2021**	**2022**	**2023**	**2024**	**TOTAL**	**No. of cases per season**

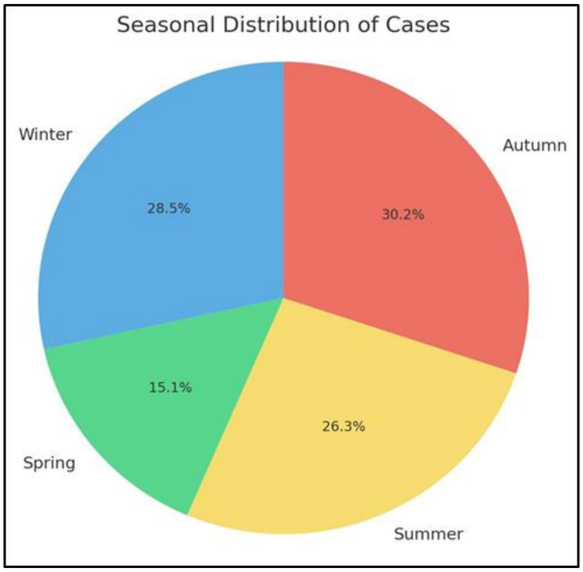
Figure 3. The percentage distribution of cases by season



The malignant skin lesions identified in this study were categorized into basal cell carcinoma (BCC), squamous cell carcinoma (SCC), and melanoma. Out of the total 388 lesions, 168 were classified as BCC (Fig. 4). Histopathological evaluation allowed for further subtyping of BCC cases. The nodular subtype was the most prevalent (n = 68), followed by the adenoid type (n = 43), superficial BCC (n = 26), and the infiltrative variant (n = 23). Rare subtypes included basosquamous, pigmented BCC, Pinkus fibroepithelioma, and infundibulocystic BCC, each represented by one or two cases. Additionally, a single case associated with Gorlin syndrome was documented. Notably, no cases of micronodular BCC were observed (Fig. 5). Regarding squamous cell carcinoma, a total of 25 cases were identified. The majority were well-differentiated SCCs (n = 16), followed by moderately differentiated SCCs (n = 8) and poorly differentiated SCCs (n = 3). No anaplastic SCCs were detected during the study period.

Figure 4. Distribution of non-melanoma skin cancers cases

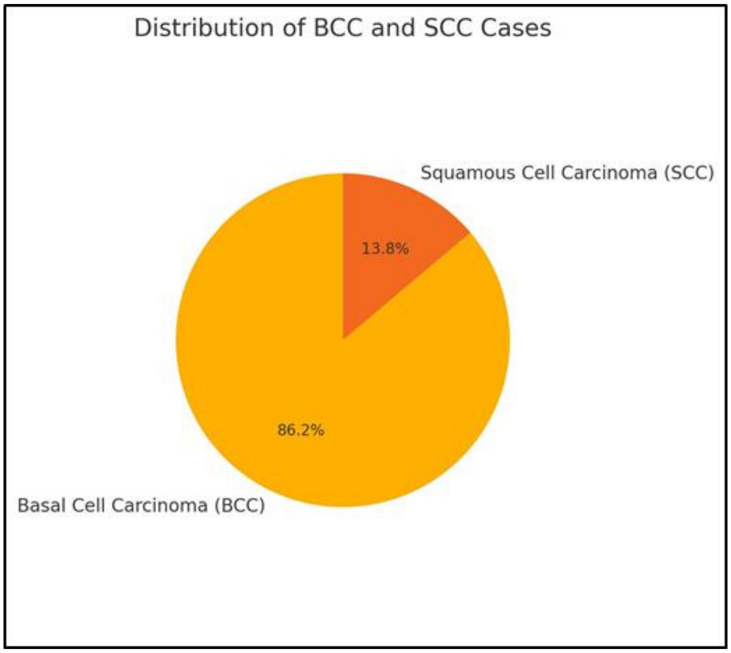


Figure 5. The incidence of histological subtypes of BCC

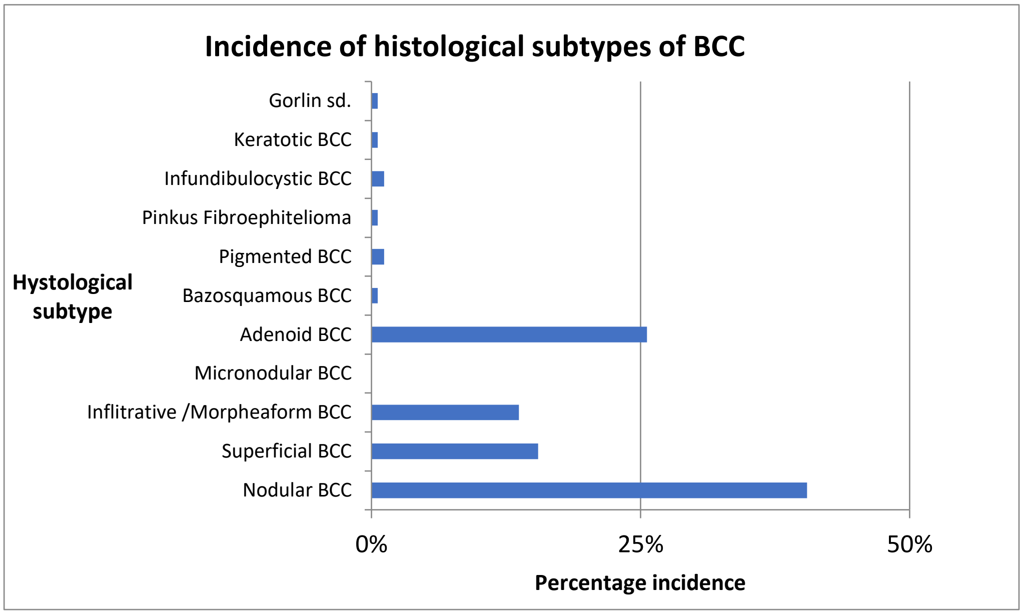
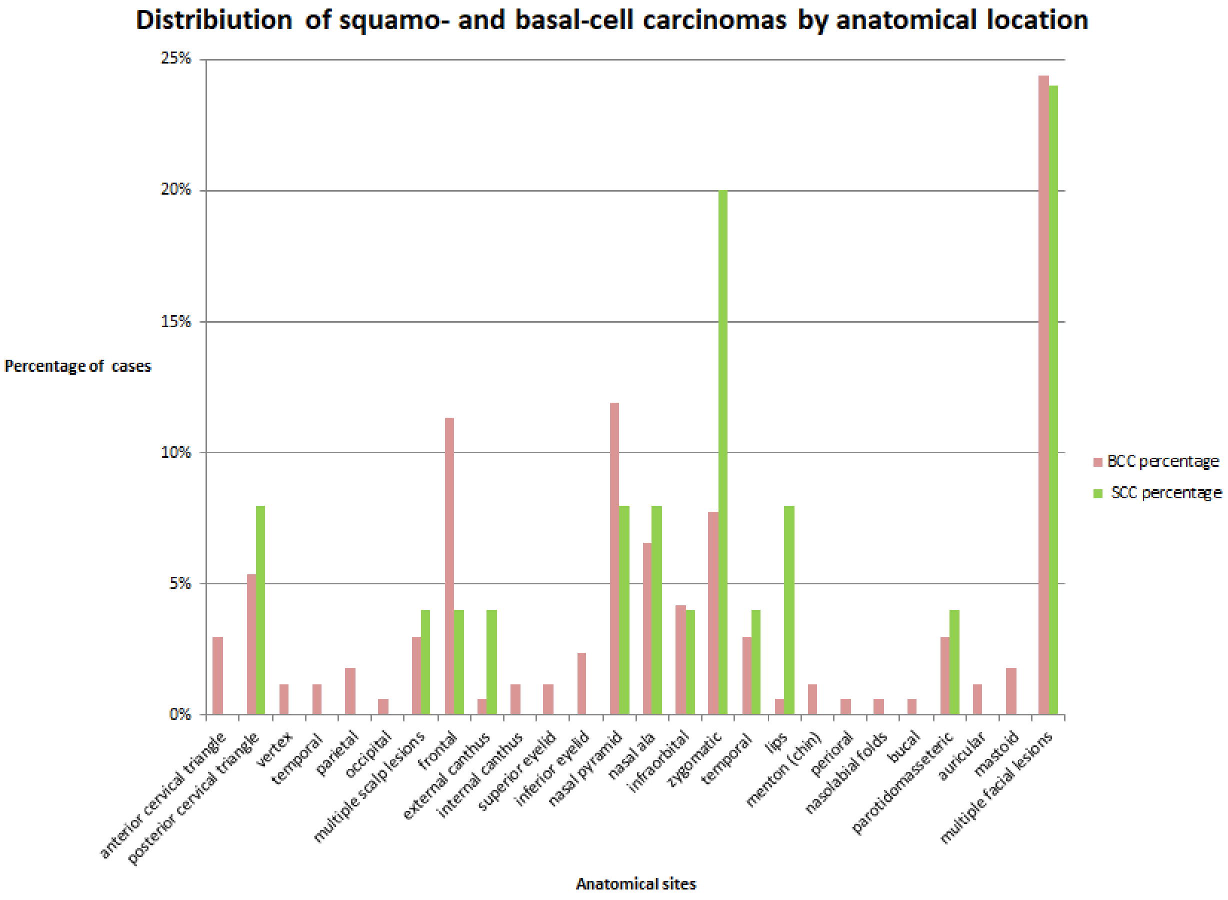


Based on the collected data, the majority of malignant lesions were located on the face (n = 152), a significantly higher number compared to those on the neck (n = 16) and scalp (n = 12). A more detailed anatomical breakdown of facial lesions revealed 20 cases on the forehead (10.3%), 23 on the nasal pyramid (11.8%), and 18 on the zygomatic region (9.2%). Additionally, 23 patients presented with multiple lesions on various facial subregions. Beyond the face, 24 other patients were identified with multiple malignant lesions distributed across the head and neck areas. Regarding the neck, the posterior cervical triangle showed a higher incidence (n = 11) compared to the anterior cervical triangle (n = 5). As for the scalp, lesion distribution was as follows: 2 cases on the vertex, 2 in the temporal region, 4 in the parietal region, 1 occipital lesion, and 3 patients with multiple scalp lesions.

When comparing the anatomical distribution of BCC and SCC, distinct patterns were observed. Several regions—including the anterior cervical triangle, vertex, temporal, , parietal, occipital, external canthus, upper and lower eyelids, chin (menton), perioral region, nasal area, auricle, and mastoid region—exhibited only BCC lesions, with no SCC cases recorded in these locations. On the forehead, 11% of all BCCs were located, compared to only 4% of SCCs, indicating a preferential distribution of BCC in this region. In contrast, the zygomatic region accounted for the highest proportion of SCC cases (20%), suggesting a predilection for SCC in this area. Within the posterior cervical triangle, SCC represented 8% of all cases found there, while BCC accounted for 5%, indicating a slightly higher occurrence of SCC in this particular region (Fig. 6).

The vertical dimension of malignant skin lesions showed notable variation across histological subtypes. Among basal cell carcinoma (BCC) types, the infiltrative/morphea form subtype had the highest mean depth (1.46 mm), followed closely by the superficial type (1.35 mm) and adenoid (solid adenoid) variant (1.30 mm). Less invasive subtypes such as nodular BCC had a mean depth of 1.21 mm, while rare variants like pigmented, Pinkus fibroepithelioma, and Gorlin syndrome-associated BCC displayed moderate vertical dimensions (ranging from 1.1 to 1.75 mm). Micronodular BCC was not reported in the dataset. In contrast, squamous cell carcinoma (SCC) subtypes tended to show greater vertical extension. Well-differentiated SCCs had the greatest average depth at 1.92 mm, while moderately differentiated SCCs averaged 0.97 mm, and poorly differentiated SCCs presented an intermediate value of 1.08 mm. These findings suggest a potential correlation between SCC grade and tumor depth.

Figure 6. Distribution of NMSC by anatomical location



Temporal analysis revealed fluctuations in lesion depth over the five-year period. For nodular BCC, the vertical dimension ranged from 1.0 mm to 1.49 mm, indicating no clear increasing or decreasing trend. A more pronounced variation was observed in the superficial BCC subtype, which reached a peak of 1.85 mm in 2022 and dropped to 1.06 mm in 2023 before rising again to 1.61 mm in 2024. Infiltrative BCCs peaked at 2.52 mm in 2022—suggesting a possible diagnostic delay or more aggressive presentation in that year. Regarding SCC, well-differentiated lesions consistently displayed greater depth than other SCC subtypes, with a maximum of 2.5 mm recorded in 2022. However, sample sizes for some years and subtypes are limited, warranting cautious interpretation.

A Mann–Whitney U test was performed to compare the vertical depth of BCC and SCC. The median depth in BCC subtypes was 2.20 mm, while SCC subtypes showed a median of 1.32 mm. The test yielded a U statistic of 129.5 and a p-value of 0.797, indicating no statistically significant difference between the two groups.

In order to assess whether there is a correlation between age and the vertical di-mension of the lesion, we applied Spearman's rank correlation test. The results (Spear-man's ρ = 0.023, p = 0.744) suggest that there is no significant association between the two variables, indicating that lesion thickness does not appear to vary meaningfully with patient age in our dataset.

A Mann–Whitney U test (which is non-parametric) was conducted to determine whether there was a difference in vertical dimension between males and females. The results indicated a statistically significant difference between the groups (U = 6473.0, p = 0.009), suggesting that sex may influence vertical dimension. The vertical dimension mean in men was 1.5 mm, while in female was 1.25 mm.

When analyzing the lesion surface area across basal cell carcinoma (BCC) subtypes, we observed considerable variability. The infiltrative/morpheiform subtype demonstrated the largest mean area, with an average of 2.47 mm², followed by the adenoid type (1.58 mm²) and nodular type (1.43 mm²). The superficial BCC subtype had a slightly higher average area (1.85 mm²) than nodular, which may reflect the lateral spread characteristic of this variant. Rare subtypes such as basosquamous/metatypical carcinoma presented a notably high mean area of 74.46 mm², although this finding is based on a single case and should be interpreted cautiously. Other rare variants, including keratotic, fibroepithelioma of Pinkus, and infundibular-cystic subtypes, exhibited relatively small areas ranging from 1.2 to 1.43 mm². The Gorlin syndrome-associated lesion had an average area of 1.55 mm².

For squamous cell carcinoma (SCC), the mean lesion areas were generally larger than most BCC subtypes. Well-differentiated SCCs demonstrated the highest average area, reaching 2.41 mm², while poorly differentiated tumors averaged 1.07 mm². Moderately differentiated SCCs had the smallest mean area among SCC subtypes at 0.77 mm².

A Mann–Whitney U test was also conducted to compare the lesion surface areas between BCC and SCC tumors. The analysis yielded a U statistic of 133.5 with a p-value of 0.60, indicating no statistically significant difference in lesion surface area between the two groups. This suggests that, despite observed differences in average lesion sizes, such as larger surface areas in some well-differentiated SCCs. These differences may be attributed to sample variability rather than a true underlying disparity in tumor size between BCC and SCC in this cohort.

There was a significant difference in lesion area between males and females (U = 6290.0, p = 0.0095) (Fig. 7). While the median lesion area was higher in males (1.0 cm² vs. 0.7 cm²), a rank-based comparison showed a small-to-moderate effect (rank-biserial r = −0.21), likely influenced by high outliers in the female group. A lesion measuring 74.46 mm in a female case was excluded from the analysis to minimize the impact of outliers and ensure that the results more accurately reflect the central tendency and variability within the dataset.

DISCUSSION

Comparing the data we collected with other clinical studies conducted in recent years in different regions of Romania, a consistent national trend in the incidence of non-melanoma skin cancers can be observed. Both a one-year 2022 study from South-Western part of the country (Craiova city) and a five-years 2014 study from the North-Eastern region (Iasi city) support and validates our findings, confirming their reliability and broader applicability. Thus, both studies indicate a prominence of basal cell carcinomas among the identified NMSC cases, with reported proportions of 55% in the 2014 study and 75,5% in the 2022 study [18,19]. Notably, the 75,5% figure closely aligns with our own findings, where BCC accounted for 86% of cases [18]. This may reflect either an increasing trend in the incidence of BCC over time, or differences in exposure to specific risk factors depending on region. Other similarities to our study include the predominance of the nodular subtype of BCC, which was the most frequently encountered variant in both comparative studies [18,19]. In our study, nodular BCC accounted for 40% of cases, closely matching the 40,4% reported in Iasi [19]. Additionally, all three studies identified the face as the most common anatomical site for tumor occurrence, which may support the correlation between UV exposure and lesion development [18,19]. Moreover, a slight female predominance was observed consistently: women represented 52% of cases in our study and 53% in the Craiova one [18]. These very similar findings highlight the potential role of common environmental and behavioral risk factors and support the need for continued epidemiological monitoring in Romania.

The observed seasonal variation, with higher incidence on non-melanoma skin cancers during autumn and lower numbers in spring, is consistent with the findings of previous studies. A 2017 study from North Carolina concluded that the diagnosis rates of BCC and SCC were highest in October and August, so at the end of the festival season, that confirmed the idea of delayed diagnosis after summer UV exposure [20]. According to Bianconi et al., the Umbria region of Italy had also a higher incidence of NMSC during autumn (mostly October), which was explained as a late cancer progression effect of UV exposure [21]. These similarities support the hypothesis that medical consultation is often delayed due to the clinical appearance of suspicious skin lesions following prolonged summer sun exposure. Consequently, many lesions are diagnosed in the following season- autumn- after cumulative sun damage becomes clinically. Given the seasonal pattern of delayed diagnosis, it is crucial to examine potential preventive measures, such as public health campaigns targeting periods of high UV exposure months. These interventions should aim to raise awareness about the risks of sun damage, promote early skin examinations, and encourage timely medical consultations.

The lack of statistical significance regarding the vertical dimension and area may be due to sample size limitations or uneven subtype representation within groups. For example, rare or extreme outliers like the metatypical BCC area (74 mm²) can skew averages and impact variability. Future studies with larger, more balanced samples may provide clearer insight into surface area differences between malignant skin lesion subtypes.

The recent Covid-19 pandemic impacted in a negative way the worldwide healthcare systems, leading to disruptions in routine medical services. As observed in Table I, there were no admissions of dermatology cases in our department between April 2020 and June 2021, which indicates that dermatological services were not operational through this period. There are several existing factors which contributed to the activity disruption. Firstly, the pandemic's health care focus likely caused resource redirection. Secondly, institutional policies mandating restriction consults of any case that is not an emergency severely capped support for patients. Another reason may be the fact that considerable sections of the medically unwell population opted not to attend medical facilities due to the high likelihood of contracting the virus, which adds even more weigh. This local experience aligns with global trends observed during the pandemic. A study analyzing data from the American Academy of Dermatology's DataDerm registry reported a significant decrease in in-person dermatology visits between April 2020 and June 2021, with a corresponding increase in tele-dermatology appointments [22]. However, expanding tele-dermatology services did not ascertain timely diagnosis and prompt treatment for a significant number of patients. Research shows lockdowns led to a diverse range of disruptions that caused cancer diagnoses to be missed on a global scale. The World Health Organization's International Agency for Research on Cancer estimated that about one million cases of cancer went undetected globally during the lockdown because of Covid-19 [23]. This statement emphasizes the need for strategies to maintain essential healthcare services even during public health crises. The increasing number of diagnoses of cutaneous cancer in the post-pandemic period, could stem from the backlog of cases that went undiagnosed when routine dermatological checkups were either postponed or unavailable.

In the present study, a statistically significant difference was observed in the vertical thickness of non-melanoma skin cancers (NMSC) between male and female patients, with mean measurements of 1.5 mm and 1.25 mm, respectively. This disparity, though numerically modest, holds substantial clinical relevance, as increased tumor thickness is associated with a higher risk of local invasion and recurrence.

Several factors may contribute to this gender-based difference in tumor presenta-tion. One of them could be considered the delayed medical consultation among men. Men are generally less likely to engage in preventive healthcare practices. According to a 2009 study, the white middle-class men were the most affected by melanoma because of the delay in seeking medical attention for skin lesions [24]. This tendency may result in the progression of tumors to greater thickness before diagnosis. Another contributing factor to the gender difference seems to be the sun protection behaviors. The American Association for Cancer Research reported in a 6 years study, that women are more likely to adopt behavioral changes as using sun protection measures like including sunscreen and protective clothing, to prevent future cutaneous cancers [25]. They would also limit more the outdoor activity and when outside, they would seek shade more than men [25]. This may contribute to earlier detection and thinner tumors at diagnosis.

Although our study shows a higher incidence of NMSC in urban areas, this finding is most likely explained by the location of the study center- a tertiary hospital in Bucharest. The majority of patients included in the study were residents of Bucharest, which leads to an overrepresentation of urban cases. This does not necessarily reflect a higher exposure to risk factors in urban settings, but rather the geographic bias introduced by easier access to specialized dermatological care in the capital. As shown in a retrospective U.S. study with patients recruited from two primary care practices in one rural Maine regional health system, rural patients often face significant barriers to dermatological evaluation and treatment [26]. That may include longer travel distances, limited availability of specialists and socioeconomic constraints.

Another point to discuss is the predominance of basal cell carcinoma in our studied population, with a higher incidence of the nodular subtype (40% of the BCC cases). These findings are aligning with the worldwide trend, as the BCC is well-known the most frequent skin cancer in adult patients with fair skin, the nodular lesions accounting for more than 60% of all BCCs [27]. Nodular subtype are usually slow growing, non-aggressive tumors, belonging to the indolent-growth subset [10]. Thus, its predominance in the studied population may indicate that most cutaneous neoplasms in fair-skin adults are having a favorable outlook. This may be explained by the commonly less aggressive nature of the nodular variant, or by the fact that they are being detected in an early stage, before becoming invasive. The last one is not a well-supported hypothesis, as we have to emphasize the frequent delay in making a definitive diagnostic due to several contributing factors like the still existing need for access to a good dermatological care for all socioeconomic groups.

Regarding squamous cell carcinoma, our study revealed a greater average vertical dimension of well-differentiated lesions (1,92mm), compared to all the mean depths of the different subtypes of BCCs. The bigger vertical growth of SCC can have potential implications in the tumor outcome, as may be an indicator for the cancer aggressiveness. According to a 2024 literature review, the cutaneous squamous cell carcinoma of the head and neck can present metastasis in approximative 2,5% of patients, most often localized in the level II lymph nodes and the parotid glands [28,29]. Unlike BCC, cSCC can spread both nearby and distant locations, one of the high-risk criteria for the metastasis being represented by a depth invasion greater than 6 mm [28,29]. Although none of the studied lesions were deeper than 6 mm, it is necessary to highlight the importance of correlating depth patterns of cSCCs with their metastatic rates and with the right choice of treatment. The primary method of treatment remains the surgical resection, but the tumor depth and size can dictate the type of therapy need to be used. The vertical dimension of cSCCs influences also the follow-up protocols, as patients with greater tumor depths (so high-risk groups) requires a tighter follow-up [29].

Lastly, although most NMSC cases are treated successfully with local excision, ad-vanced or recurrent head and neck lesions (particularly large or deep infiltrating squamous cell carcinomas) may require complex surgical resections. In such cases, reconstruction becomes critical not only for functional and aesthetic restoration but also for maintaining the patient’s quality of life. Free flaps and other advanced reconstructive techniques, such as the radial forearm or anterolateral thigh flap, offer valuable options. The success of these procedures underscores the importance of surgical expertise and a multidisciplinary approach, as emphasized in recent scoping reviews. [30]

Our study's possible limitations should be taken into account when interpreting the results as they may have introduced bias. Since only 180 patients were chosen from a single tertiary medical center, the study had a relatively small sample size and was carried out over a five-year period. Since it ignores possible variations in clinical, histo-pathological, or demographic characteristics among various populations or geographical areas, this may lower its statistical power and have an impact on the findings' generalizability. Furthermore, the COVID-19 pandemic coincided with a portion of the study, which disrupted data collection and resulted in fewer patients having access to medical services. Clinical activity was interrupted by these contextual factors, resulting in missing or insufficient data. Notwithstanding these drawbacks, our research still provides insightful information.

Nevertheless, we emphasize the very actual need of further prospective studies which should assess the targeted screening programs influence in early cancer detection and diagnosis, and the effectiveness of different treatment strategies in patients with head and neck non-melanoma skin cancers.

CONCLUSIONS

The study identified a progressive increase in the incidence of malignant skin lesions from 2020 to 2023, followed by a decrease in 2024. This trend could be attributed to factors such as the impact of the COVID-19 pandemic on healthcare access and a possible post-pandemic surge in cases. Continued monitoring is essential to validate whether this trend persists in subsequent years.

The analysis revealed a statistically significant variation in skin cancer diagnoses across seasons, with the lowest incidence observed in spring and relatively similar fre-quencies in summer, autumn, and winter.

The face was the most common location for malignant lesions, emphasizing the significant role of sun exposure in the etiology of NMSC. BCC was the most frequent histological subtype, with nodular BCC being particularly prevalent. In contrast, SCC, although less common, demonstrated greater metastatic potential and depth, especially the well-differentiated subtype.

Our analysis revealed statistically significant differences in lesion size between sexes, with both area and vertical dimensions being greater in males compared to fe-males.

The majority of NMSC cases were recorded in urban areas, particularly Bucharest, suggesting a potential link between urban living and higher skin cancer incidence or, conversely, a lack of adequate healthcare access in rural regions. Additionally, while the sex distribution was relatively balanced, males exhibited significantly greater lesion depths compared to females.

Abstract: Neuroendocrine tumors (NETs) are a group of rare malignancies characterized by heterogeneous clinical and biological presentations. Their estimated annual incidence ranges from 3 to 6 cases per million inhabitants, with a notable rise in prevalence due to improved diagnostic capabilities and medical awareness. Gastrointestinal NETs predominantly affect the small intestine (~45%), followed by the rectum, appendix, colon, and stomach. Despite advancements in imaging modalities such as CT, MRI, and somatostatin receptor-based PET-CT scans, the diagnosis of small intestinal NETs remains challenging due to nonspecific symptoms, frequently leading to delayed recognition until advanced disease stages. Surgical resection with comprehensive lymphadenectomy remains the cornerstone of curative management for localized disease, offering improved survival outcomes when R0 resection is achieved. Nevertheless, recurrence rates remain high, underscoring the critical importance of postoperative surveillance. This review provides a comprehensive synthesis of recent literature regarding the epidemiology, clinical manifestations, diagnostic methods—including imaging and immunohistochemical markers—and therapeutic approaches, particularly emphasizing surgical management strategies. A clinical case example is integrated into the review to illustrate the real-world complexity and challenges in the diagnosis, treatment, and follow-up of patients with small intestinal NETs.

Keywords: multiple gastrointestinal neuroendocrine tumors, small intestine, nonspecific abdominal pain

INTRODUCTION

Gastrointestinal neuroendocrine tumors (NETs) are rare, slow-growing tumors characterized by specific histological, biological, and clinical features. These tumors have shown a significant increase in incidence and prevalence over recent decades, reaching an increase of over 100% in the past 40 years, due to advancements in diagnostic methods and increased medical awareness [1-6]. Gastrointestinal NETs represent an important subtype of neuroendocrine tumors, affecting various segments of the gastrointestinal tract, as follows: the small intestine (45%), rectum (20%), appendix (16%), colon (11%), and stomach (7%) [7].

One of the most notable characteristics of these tumors is their predominant setting in the small intestine, particularly in the terminal ileum, approximately 60 cm from the Bauhin valve. This makes them the most frequent malignancy of the small intestine [8]. Small intestinal neuroendocrine tumors are often diagnosed in advanced stages because clinical symptoms are frequently nonspecific and can include abdominal pain, intestinal obstruction, and symptoms caused by carcinoid syndrome [2]. Additionally, these tumors develop distant metastases more frequently than neuroendocrine tumors from other locations, further complicating their clinical management. Mesenteric lymph node metastases are found in over 80% of patients at the time of diagnosis, regardless of the primary tumor's size [9-14]. Imaging techniques such as contrast-enhanced CT, MRI, and somatostatin receptor-based PET scans have improved detection, while immunohistochemical markers such as chromogranin A and synaptophysin aid in confirming the diagnosis.

Histologically, gastrointestinal neuroendocrine tumors are characterized by the presence of neuroendocrine cells that secrete various peptides and biogenic amines. These substances can cause diverse clinical manifestations, including diarrhea, flushing, and wheezing, within the context of carcinoid syndrome [15].

Biologically, the tumors exhibit variable expression of neuroendocrine markers such as chromogranin A and synaptophysin, which are used in the diagnosis and monitoring of the disease [7, 16-18].

Recent studies have highlighted the genetic and molecular diversity of gastrointestinal neuroendocrine tumors. Mutations in the MEN1, DAXX, and ATRX genes are frequently associated with these tumors. The identification of these mutations has allowed for a better understanding of the tumor pathogenesis and opened new perspectives for targeted therapies [8, 19-21].

The clinical management of patients with gastrointestinal neuroendocrine tumors involves a multidisciplinary approach, including advanced imaging, endoscopic techniques, surgery, and systemic therapies. Surgical intervention remains the treatment of choice for resectable tumors [22], while systemic therapies, including somatostatin analogs, mTOR inhibitors, and radionuclide therapies, are used for advanced or metastatic disease [23-29].

EPIDEMIOLOGY AND DEMOGRAPHICS

Gastrointestinal neuroendocrine tumors (NETs) represent a relatively rare group of malignancies, yet recent literature indicates a significant rise in their incidence worldwide. Small intestinal NETs account for approximately 45% of all gastrointestinal NETs, establishing these tumors as the most prevalent malignancy of the small bowel [1,7]. The estimated global annual incidence ranges between 3 to 6 cases per million inhabitants, with a clear upward trend observed over the last four decades, primarily attributed to improved diagnostic methods and increased physician awareness [2,4].

A comprehensive analysis of epidemiological data from the Surveillance, Epidemiology, and End Results (SEER) database (1977–2016) by Liu et al. (2023) demonstrated that gastrointestinal NETs have exhibited a dramatic increase of over 100% in diagnosed cases during recent decades [2]. This significant upward trend reflects advances in diagnostic imaging modalities and improved endoscopic techniques, facilitating earlier and more accurate diagnosis [2,7].

In line with findings reported by Taal and Visser (2004), small intestinal NETs show notable geographical variation, yet consistently demonstrate an annual incidence ranging from 3 to 6 cases per million inhabitants globally [4]. This consistency suggests a common biological behavior and potentially shared risk factors influencing the occurrence of these tumors [4-5].

Epidemiological patterns also reveal that the diagnosis of small bowel NETs most commonly occurs between the ages of 50 and 70 years, highlighting the importance of clinical suspicion within this age group when nonspecific gastrointestinal symptoms are present. The age distribution emphasizes the need for targeted diagnostic vigilance in middle-aged and older patients presenting with chronic abdominal complaints without an obvious etiology [6-7,12].

In addition, several retrospective studies have documented the high likelihood of delayed diagnosis due to nonspecific symptomatology, often resulting in advanced disease at initial presentation, with a high frequency of mesenteric lymph node involvement and distant metastasis at the time of diagnosis [6-7].

Therefore, awareness of these epidemiological trends, along with improved understanding of the disease's clinical behavior, is crucial for clinicians to achieve earlier diagnosis and intervention, ultimately enhancing patient outcomes.

CLINICAL PRESENTATION AND DIAGNOSIS

The clinical presentation of gastrointestinal neuroendocrine tumors (NETs), especially those of the small intestine, is highly variable and nonspecific, frequently contributing to significant delays in diagnosis. Commonly reported symptoms include chronic abdominal pain, often intermittent and vague, unexplained weight loss, changes in bowel habits such as chronic diarrhea or intermittent constipation, and episodes of intestinal obstruction due to either tumor mass or mesenteric fibrosis [7,25,27].

In certain instances, especially when tumors exhibit secretory activity (functional NETs), clinical presentation may include symptoms associated with the classic carcinoid syndrome. This syndrome occurs predominantly when liver metastases are present, allowing serotonin and other vasoactive substances to enter systemic circulation. Characteristic features include episodic flushing, chronic diarrhea, bronchospasm, and occasionally cardiac valvular lesions [15,29].

The nonspecific clinical picture typically leads to prolonged diagnostic latency, with literature reporting that many cases are incidentally identified during surgeries performed for unrelated reasons, such as intestinal obstructions or abdominal hernias, rather than direct suspicion of NETs [25,27].

Imaging plays a crucial role in diagnosing NETs and determining disease extent. Computed tomography (CT), Magnetic Resonance Imaging (MRI), and somatostatin receptor imaging (68Ga-DOTATATE PET/CT) are the mainstay diagnostic tools. Of these, somatostatin receptor PET-CT (68Ga-DOTATATE PET-CT) has demonstrated superior sensitivity and specificity, especially for detecting small primary tumors and distant metastases compared to conventional imaging methods [3,8].

Histopathological confirmation is indispensable for accurate diagnosis and characterization of NETs. Immunohistochemical markers such as chromogranin A, synaptophysin, and the transcription factor CDX2 are routinely employed and demonstrate high sensitivity and specificity for neuroendocrine differentiation [3,6].

Additionally, the proliferation index assessed by the Ki67 index is crucial in grading these tumors and assessing their malignant potential. The World Health Organization (WHO) classification categorizes NETs as G1 (Ki67 <3%), G2 (Ki67 3-20%), or G3 (Ki67 >20%), directly impacting the choice of therapeutic strategies and prognostic evaluation [6,12,22].

Given the nonspecific nature of the symptoms, the combination of clinical suspicion, advanced imaging modalities, and specific immunohistochemical analyses is paramount to timely diagnosis and improved outcomes for patients with small intestinal NETs.

Surgical management of small intestinal neuroendocrine tumors

Surgical intervention remains the cornerstone of management for localized small intestinal neuroendocrine tumors (SI-NETs). The primary goals of surgical treatment include complete tumor resection (R0 resection), adequate lymph node dissection, and alleviation of symptoms associated with tumor burden or obstruction.

Given that SI-NETs frequently present with multifocal lesions (25-44% of patients), a thorough exploration and palpation of the entire small intestine from the ligament of Treitz to the ileocecal valve is critical to achieve adequate surgical clearance. Consequently, open laparotomy remains widely accepted as the gold standard, as it allows complete assessment and palpation to detect subcentimeter tumors that are often missed by minimally invasive techniques [9,14,23-27,28].

Despite this, several studies have explored the efficacy of minimally invasive approaches such as laparoscopy. Figueiredo et al. (2014) described laparoscopic resection of small-bowel NETs in a cohort of 12 patients, demonstrating comparable outcomes in selected cases. Similarly, Reissman et al. (2013) successfully employed laparoscopic resections in 20 patients with primary midgut carcinoid tumors, emphasizing the feasibility and safety of this method in carefully selected cases. However, both studies highlighted critical limitations, notably the difficulty in detecting sub-centimetric lesions, which may necessitate additional techniques such as hand-assisted laparoscopy or open exploration to achieve complete resection [25-27].

Comprehensive lymphadenectomy is also a fundamental aspect of surgical treatment, as metastases in mesenteric lymph nodes are present in more than 80% of patients at initial diagnosis. Optimal lymph node dissection has demonstrated improved long-term outcomes and decreased recurrence rates. Motz et al. (2018), in a comprehensive retrospective analysis from the National Cancer Database (NCDB), emphasized that thorough lymphadenectomy significantly correlates with improved survival outcomes, particularly when combined with R0 resections [10-11,28].

Following curative surgery, long-term follow-up is essential due to the notably high recurrence rate, estimated around 50% even after achieving an R0 resection. Le Roux et al. (2011), in a large multicenter French retrospective analysis, highlighted that factors such as tumor size, presence of lymph node metastases, and microscopic residual disease significantly increase the risk of recurrence. Regular postoperative surveillance involving biochemical markers, such as chromogranin A, and imaging modalities, including CT and somatostatin receptor PET-CT, is therefore mandatory to ensure early detection of recurrence and prompt therapeutic intervention [29-33].

In summary, optimal surgical management of small bowel NETs requires careful evaluation and meticulous surgical techniques, aiming at complete resection (R0) and adequate lymph node clearance. Given the frequent recurrence even after successful surgery, ongoing surveillance and follow-up are critical components in the comprehensive management of patients with SI-NETs.

Case example: multifocal small intestinal net

A 68-year-old male, with history of right inguinal hernia surgery in 2005 and no significant family medical history, who has been exposed to toxic environment, presents to our department complaining of diffuse abdominal pain amplified in the left lower quadrant, particularly postprandial, anorexia, the presence of a left inguinal pseudotumoral mass, and 15 kg weight loss in the last 3 months.

The symptoms began approximately 2 months before admission, with severe abdominal pain, predominantly in the left lower quadrant, unresponsive to usual analgesics, anorexia, intestinal motility disorders – loose stools in the last 3 weeks, weight loss – 15 kg in 3 months, and 2 episodes of minor upper gastrointestinal bleeding.

The patient was evaluated in another medical center through upper gastrointestinal endoscopy, lower gastrointestinal endoscopy, and no significant findings. Abdominal ultrasound showed a left lower abdominal quadrant mass.

The patient presented to the Surgery Department of “Dr. Carol Davila” University Central Emergency Military Hospital, in an emergency setting, with a left lower quadrant mass, painful, enlarged (7/8 cm), irreducible, with normal overlying skin and a diffusely painful abdomen.

Subsequent investigations were performed. Thoracic-abdominal-pelvic CT scan revealed a left inguinal hernia with a 4.5 cm abdominal wall defect, narrow neck, and larger herniating sac containing omentum and a large bowel loop. There were proximal intestinal obstructive changes and colonic distension with stasis content and air-fluid levels. Additionally, a tumor mass was identified in the intramesenteric mesogastric region, antero-left para-aortic, cranial to the iliac bifurcation, measuring approximately 5/4/3 cm. The mass had a heterogeneous structure with hypodense areas included and no surgical cleavage plane to the loco-regional digestive loop.

The patient underwent emergency surgery, consisting of exploratory laparotomy. Intraoperatively, an intense adhesive process (Figure 1), multiple whitish jejunal tumor masses up to 3 cm in size, with two mesenteric tumoral masses measuring 3 cm and 5 cm in diameter with adherence to neighboring loops and incarcerated left inguinal hernia (Figure 2) were found, without ascites and no peritoneal or liver nodule. Extensive enterectomy with side-to-side entero-enteric anastomosis and non-mesh hernia repair were performed (Figures 3, 4). There were no signs of ischemia in the bowel loop contained within the herniated sac, hence, there was no need for resection. The non-mesh surgical technique was preferred in order to prevent the risk of infection associated with the mesh.

During hospitalization, the patient had a favorable evolution and was discharged on the 7th postoperative day.

Figure 1: Abdominal adhesions

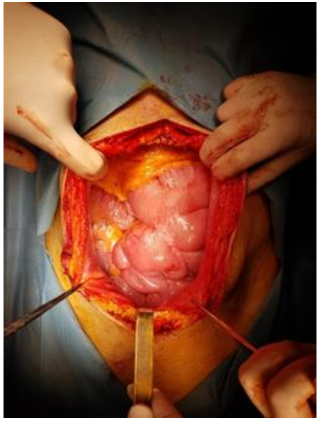

Figure 2: Mesenteric tumoral mass

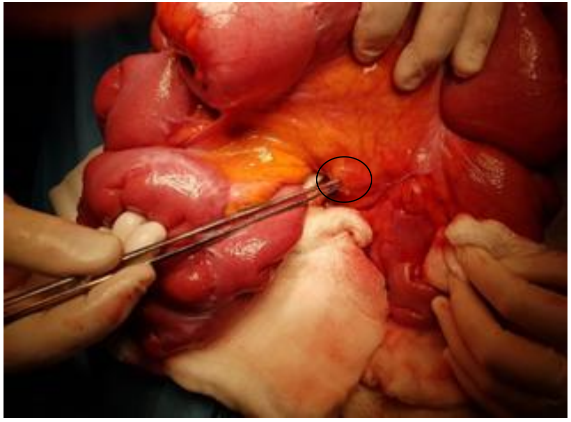

Figure 3: Side-to-side anastomosis

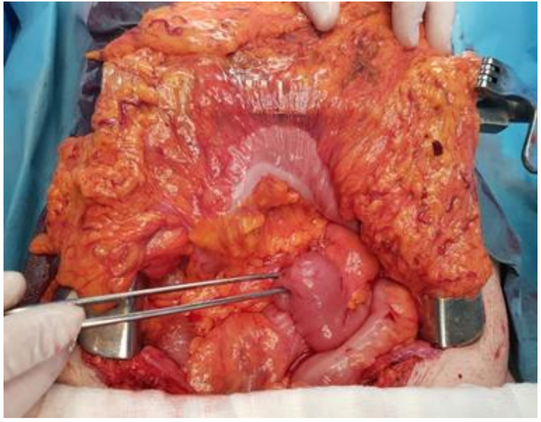

Figure 4: Resected specimen

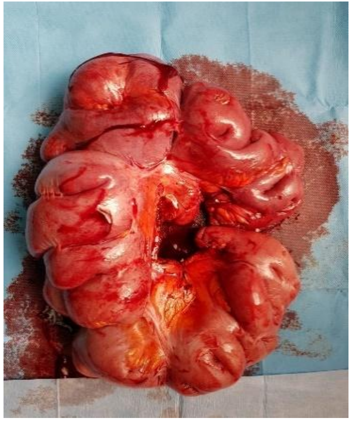

Histopathologic result confirmed the diagnosis of neuroendocrine tumor involving multiple levels of the small intestine with lymph node metastases (3/10) (TNM: pT4 N2 Mx).

The immunohistochemical examination revealed that CDX2 (EPR2764Y) exhibited a uniform positive reaction with both intensity and distribution in the tumor cells, indicating consistent expression throughout the sample. Similarly, CHROMO (LK2H10) showed a uniform positive reaction with intensity, while Synaptophysin (SP11) demonstrated a uniform positive reaction with diffuse intensity in the tumor cells, suggesting widespread expression. Furthermore, Ki67 (30-9) displayed an intense nuclear reaction in 1% of the tumor cells, indicating a low proliferative index within the examined sample. These findings collectively support the diagnosis and provide insights into the tumor's characteristics.

Table 1: Immunohistochemical results

CDX2 (EPR2764Y): Uniform positive reaction with intensity and distribution in tumor cells
CHROMO (LK2H10): Uniform positive reaction with intensity in tumor cells
Synaptophysin (SP11): Uniform positive reaction with intensity, diffuse in tumor cells
Ki67 (30-9): Intense nuclear reaction in 1% of tumor cells

Immunophenotypic data correlated with the morphological cells in the examined fragment are compatible with a neuroendocrine tumor of reduced histological grade (G1).

The patient did not receive chemotherapy, somatostatin analogues, or radiotherapy. He underwent routine follow-ups and regular imaging investigations. At the five-year evaluation, no tumor recurrences or new pathological findings were detected.

DISCUSSION

Primary tumors in the jejunum or ileum are frequently very small, requiring meticulous palpation of the small intestine from the ligament of Treitz to the ileocecal valve. In 25% to 44% of patients, there are multifocal primary tumors, many of which are subcentimeter in size and can only be detected through careful digital palpation [24]. The use of laparoscopy in these cases is controversial, as it may not allow the detection of such small tumors and does not enable the comprehensive palpation of the entire small intestine that is essential for identifying multifocal disease. Therefore, the limitations of laparoscopy must be taken into account when determining the surgical strategy for these patients. The literature contains limited studies on the laparoscopic resection of small bowel neuroendocrine tumors (SBNETs). Figueiredo et al. [25] reported successful laparoscopic resections in 12 patients, while Reissman et al. [26] documented similar success in 20 patients. Wang et al. [27] described successful laparoscopic or minimally invasive resections of ileal neuroendocrine tumors (NETs) in six patients who presented with NETs of unknown primary origin. In their study, the authors highlighted the critical role of palpation during minimally invasive surgery to identify the small, often multifocal primary tumors. To facilitate this, they employed a hand-assisted laparoscopic device or a soft tissue wound retractor to exteriorize the jejunum and ileum. This technique allows for comprehensive palpation, resection of the primary tumors, dissection of mesenteric lymph nodes and associated fibrosis, and subsequent intestinal anastomosis.

Current literature regarding the optimal management of neuroendocrine tumors recommends achieving an R0 resection to increase survival rates. However, an R0 resection is feasible in only 20% of cases due to the typically advanced stage at diagnosis [28]. It is important to highlight that the patient presented as an emergency case with symptoms caused by intestinal obstruction due to an incarcerated inguinal hernia, and not from the intestinal tumors, which were discovered incidentally. Therefore, it cannot be claimed that there was an intent for radical treatment, even though an R0 resection was achieved.

Adjuvant treatment options for neuroendocrine tumors may include chemotherapy, somatostatin analogues, and radiotherapy. However, following curative surgery for small intestinal neuroendocrine tumors, there is no established benefit for adjuvant systemic therapy. Somatostatin analogues are recommended for their antiproliferative properties as a first-line treatment for slowly progressive, well-differentiated metastatic small intestinal neuroendocrine tumors. Additionally, they are used for antisecretory purposes to manage persistent secreting syndromes or refractory diarrhea by inhibiting gastrointestinal secretions [29-31].

The overall survival rate appears favorable when compared to other malignancies. However, achieving reliable survival data is challenging due to variations in terminology, inconsistencies in coding practices, conflicting results from smaller cohort studies, and recent advancements in treatment modalities [32].

Several studies have indicated that the long-term recurrence rate for small intestinal neuroendocrine tumors (SI-NETs) following curative R0 resection, in the absence of distant metastases, is approximately 50%. This high recurrence rate underscores the need for vigilant postoperative surveillance and ongoing management strategies to monitor for disease recurrence. Factors contributing to this recurrence include residual microscopic disease and the inherent biological behavior of SI-NETs. Consequently, patients require comprehensive follow-up protocols, including regular imaging and biochemical assessments, to promptly identify and address any recurrence or progression of the disease [33].

CONCLUSION

The case highlights the importance of considering gastrointestinal neuroendocrine tumors in the differential diagnosis of nonspecific abdominal pain.

Advancements in diagnostic and treatment methods have significantly improved the outlook for many patients with NET, but challenges remain, especially for advanced or poorly differentiated cases.

Although neuroendocrine tumors are rare, their increasing incidence and clinical complexity underline the need for a multidisciplinary approach for effective diagnosis and treatment. Progress in the genetic and molecular understanding of these tumors has opened new avenues for targeted therapies, offering improved hopes for patients.

Conflicts of interest and sources of funding

The authors declare no conflict of interest. No artificial intelligence automatically generated text was inserted in this manuscript, and no image was previously published in another journal or is under consideration for publication elsewhere. This research received no external funding.

Authors' contribution

MT, BI, JC, HS performed the surgical procedure. MT contributed to the manuscript's conceptualization, methodology, investigation, discussion, review, editing, and supervision. BI contributed to the conceptualization, investigation, data curation, review, and writing of the manuscript. JC contributed to the manuscript's conceptualization, investigation, review, and editing. HS contributed to the editing and review of the manuscript. All authors have read and agreed to the published version of the manuscript.

Ethics approval and consent to participate

The study was conducted under the Declaration of Helsinki. The research was conducted under ethical guidelines and regulations, ensuring compliance with all necessary protocols.

Patient consent for publication

Written informed consent has been obtained from the patient to publish this paper.

Abstract: Combat aircraft pilots operate in highly demanding environments where their expertise and psychophysiological responses impact performance. This study evaluated the acute psychophysiological effects of simulated and real combat flight maneuvers. Twelve Spanish Air Force fighter pilots (mean age = 33.08 ± 5.21 years) participated, averaging 13.25 ± 5.15 years of military service, including deployments in international missions. Various physiological and metabolic variables—isometric hand strength, lower body strength, pulmonary capacity, blood oxygen saturation, urinary hydration levels, cortisol, and blood lactate concentrations— were measured before and after both simulated and real combat flights. Results showed no statistically significant differences between real and simulated flights for most variables, including blood oxygen saturation, lactate, glucose, cortisol, urine color, and physical fitness indicators. However, glucose levels significantly decreased after simulated flights ($p = 0.021$), and horizontal jump performance improved post-real flights ($p = 0.004$). The similarity in physiological responses suggests that simulators effectively replicate real combat conditions, reinforcing their value as a safe, effective training tool. Simulators enhance pilot preparedness while minimizing exposure to combat risks. These findings contribute to aviation psychophysiology, improving training protocols and operational readiness for both military and civilian applications, ultimately optimizing pilot performance and safety in high-risk environments.

Keywords: combat flight, fighter pilots, psychophysiological response, flight simulation, operational training

INTRODUCTION

The operational limits of military personnel are frequently challenged in a range of extreme scenarios, including parachute operations (both High Altitude High Opening [HAHO] and High Altitude Low Opening [HALO]), engagements in symmetrical and asymmetrical warfare, subterranean missions, and close-quarters combat situations. Among these, combat aviation is widely regarded as one of the most physiologically and psychologically taxing environments. Military pilots are exposed to both acute and chronic stressors, such as heightened autonomic nervous system activity, pronounced cardiovascular and hemodynamic responses, and sustained exposure to gravitational accelerations (G-forces), which can exceed 9G during high-intensity maneuvers. These conditions can substantially compromise functional capacity, manifesting in acute loss of consciousness, grey-out episodes, spatial disorientation, and blackouts, even when utilizing oxygen supplementation systems and G-suits. Furthermore, combat aviators must operate at altitudes exceeding 15 kilometers (~50,000 feet), with cabin pressurization and the administration of supplemental oxygen typically required above 7 kilometers (~20,000 feet) to mitigate the dangers associated with hypoxia and decompression illness during tactical missions [1,2,3,4,5].

Exposure to acute psychophysiological stress elicits pronounced sympathetic nervous system activation, increases in anaerobic metabolism—as evidenced by elevated blood lactate concentrations—and disturbances in several cognitive domains, including cortical arousal, memory retention, temporal perception, and perceived exertion. Repeated exposure to such stressors can induce habituation, which is associated with attenuated physiological responses and improved task performance. However, when stress exposure is prolonged and recovery is inadequate, this may result in deleterious long-term effects on both physiological and psychological health. As such, implementing training strategies that closely

mimic the stressors encountered in combat within a controlled setting is essential to enhance both operational effectiveness and the overall well-being of military personnel and aviators [5,6,7,8].

In this context, simulation-based training has gained increasing recognition as a method to reproduce the multifaceted stressors characteristic of combat environments. In aviation, flight simulators are commonly employed to replicate conditions such as high-G exposure, complex tactical maneuvers, and the cognitive load inherent to aerial combat. These simulated environments enable pilots to adapt to task-specific challenges without facing the direct risks associated with live combat operations. Prior investigations have demonstrated the utility of such simulators in assessing variables like mental workload, spatial orientation, and perceptual illusions under stress-inducing conditions. Nonetheless, despite their widespread implementation, research remains limited regarding the extent to which simulators replicate the full spectrum of psychophysiological responses observed during actual combat aviation [6,7,8,9].

Existing literature examining the physiological demands of real combat aviation has largely focused on variables such as G-force exposure, hypoxia, and the cumulative stress of extended tactical engagement. These studies have documented substantial physiological strain on the respiratory and muscular systems, as well as on metabolic processes, with measurable alterations in biomarkers such as lactate and cortisol. In contrast, flight simulators are engineered to recreate these stressors predominantly at a cognitive level, often falling short of reproducing the mechanical and gravitational stresses encountered in real flight. Although some findings suggest simulators effectively induce mental stress, there is insufficient empirical evidence to support their capacity to fully emulate the psychophysiological impact of actual combat flying [10,11,12].

A comprehensive understanding of the differential psychophysiological responses elicited by real versus simulated combat flight is imperative for refining pilot training regimens and operational planning. Given the considerable implications for pilot health and mission effectiveness, accurate replication of combat-induced stress in training environments is of paramount importance. This study seeks to address a notable gap in the current literature by directly comparing the physiological and metabolic responses of fighter pilots engaged in both real and simulated combat maneuvers. The outcomes of this research have the potential to inform the development of optimized training protocols, thereby enhancing preparedness for the demands of aerial warfare.

Accordingly, the present study hypothesizes that real combat flight induces significantly greater acute psychophysiological stress in pilots compared to simulated flight conditions. This hypothesis is grounded in the premise that, although simulation technologies are capable of replicating many cognitive stressors, they are inherently limited in their ability to reproduce the physical elements of combat aviation, including the effects of G-forces and mechanical loading. Elucidating these distinctions is essential for the advancement of simulation-based training strategies that adequately reflect the realities of combat flight.

MATERIALS AND METHODS

Participants

To achieve the objective of this research we analyzed the physiological response of fighter pilots before and after a simulated and real attack flight maneuver.

A total of 12 fighter pilots (age=33.08±5.21) from the Spanish Air Force participated in this cross-sectional study. Participants had mean military service experience of 13.25 ± 5.15 years, with experience in international missions in the current conflict in Lebanon, Afghanistan, Bosnia, Kosovo, and Iraq. Before participation, the experimental procedures were explained to all the participants, who gave their voluntary written informed consent in accordance with the Declaration of Helsinki. In addition, All the procedures were approved by the University research ethics committee (approval number: 206/219), and all participants agreed and gave written consent to participate in the study. Participants were equipped with the standard flying suit and boots, combat gear composed of parachute harness, life support jacket, and G-suit with a total weight of 10kgs.

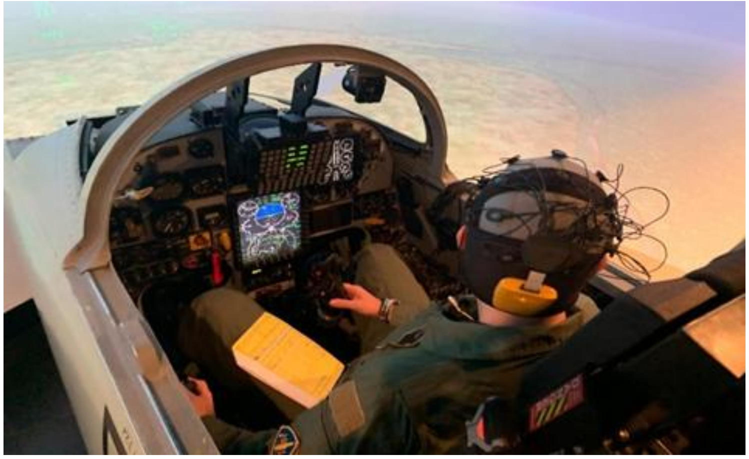
Procedures

Pilots were evaluated before and after a real fight mission and a simulated one. Conditions, protocols, and procedures were exactly the same either in simulated or real combat. F5 combat aircraft was used for the real manoeuvres (Figure 1). For the simulated maneuvers, an operational F-5 M (Indra Company, Madrid, Spain) flight simulator was used (Figure 2). All pilots conducted both protocols, and 48 hours of rest between them were assigned. The tactical combat maneuvers were performed in the Air Fighting School of the Spanish Air Force at Talavera de la Real Air Base (Badajoz, Spain), in the middle of April month, between 08:00 and 15:00, with temperatures between 20 and 24 ºC and clear sky. Order and type of protocol were also randomized, in both cases, the protocol consisted of:

In both cases, pilots conducted both maneuvers at altitudes between 8000 and 18,000 ft, with G force between 0.5 and 5.9, with oxygen mix supply over 8000 ft with a combat duration between 30 and 35 min. The offensive maneuver consisted of a fighter aircraft that started at a 1-mile separation and a speed of 400 knots (unit of speed equal to one nautical mile). Both aircraft maintained a sustained rate of 410 knots and 5.5 Gs for 30 to 40 seconds until the target aircraft (referred to as the 'bandit') was within effective gun range. By this point, the bandit had closed the distance to the offensive aircraft, causing the speed to drop to 350–300 knots and the G-load to decrease to 4–4.5 Gs. After the initial bullet stream, a repositioning maneuver could be performed to solve range, aspect, and closure. Speed will decrease to 300 knots and gravity forces to 3G's to return to a control position of effective gun employment. The exercise started at 16000 ft and it progressively decreased to 10,000 ft. In the defensive maneuver, the lead aircraft turned to one side to keep the pursuing offensive aircraft in sight. The exercise began at an altitude of 17,000 feet and a speed of 350 knots. Defensive aircraft executed a break turn at 4 G's slowing down at the same time, looking over the shoulder at the offensive aircraft to assess his pursuit curve. At 300 knots, the defensive aircraft executed turning maneuvers, gradually reducing G-forces from 3.5 to 2 Gs and speed to 200–250 knots. Depending on the progression of the air combat, the defensive aircraft could maintain an airspeed of 350 knots and a G-load of 3.5–4 Gs while descending. Exercise finished at 10000 ft.

Figure 1: F5 combat aircraft

Figure 2: F5 Indra Company (Madrid, Spain) flight simulator



Materials

One hour before and thirty minutes after finishing the air combat maneuvers the following variables were measured:

Lower body muscular strength employing horizontal jump test. Subjects performed a standardized warm-up consisting of 2x10 vertical jumps and then, they performed two maximal horizontal jumps as in the previous report (-), and the best attempt was used for the statistical analysis.

The forced expiratory volume in the first second (FEV1) corresponds to the maximum volume of air exhaled in the first second of the FVC. And mean expiratory flow or FEF25-75, which is between 25% and 75% of the forced expiratory maneuver. Were analyzed using a QM-SP100 (Quirumed, Spain) spirometer in a maximum inhale-exhale cycle.

Urine samples were collected to analyze dehydration levels which were examined by the urine color (UC) chart (color range 1-8; where 1 = very pale-yellow urine, reflected a good level of hydration, and 8 = very dark yellowish-brown, reflected a significant level of dehydration); the number closest to the sample color was recorded.

Isometric hand strength (IHS) by a grip dynamometer (Takei Kiki Koyo, Japan).

Blood oxygen saturation ($SatO_2$) and heart rate (HR) by a pulse oximeter (Pulse Oximeter 30 Beurer Medical).

Lactate and glucose samples were collected by taking a sample of 5 µl of capillary blood from the fingers of the pilots and analyzed by Accutrend Plus (Roche Diagnostics, Switzerland).

Direct Salivary Melatonin ELISA (Bühlmann, Schönenbuch, Switzerland) was used to measure cortisol concentrations.

Statistical analysis

Wilcoxon signed-rank test was used to examine the difference between the pre and post-measures. The baseline was subtracted to post-values to normalize and compare the acute effects of real vs. simulated flight. Effect sizes [r] were calculated for the non-parametric tests which are classified as follows: 0.5 is a large.

RESULTS

The results of the study revealed notable differences between the acute psychophysiological effects of real and simulated combat flights on specific metabolic, respiratory, and physical fitness variables. A significant reduction in glucose levels was observed following simulated combat flights (p = 0.021, effect size = 0.668), while this effect was not present after real flights. This finding suggests that the metabolic demands in simulated conditions may differ from those experienced during real combat maneuvers. Additionally, a significant improvement in horizontal jump performance was found after real flights (p = 0.004, effect size = 0.839), indicating enhanced lower body strength or neuromuscular efficiency induced by real combat flight conditions.

No significant differences were detected in other variables, including blood oxygen saturation, blood lactate levels, cortisol concentrations, urine color, respiratory function (FEV1, FER25, FEF75), or handgrip strength, either between pre- and post-measurements or when comparing real and simulated flight conditions. These results highlight the comparable physiological demands of simulated and real combat flights across most variables, emphasizing the potential of simulation-based training to closely replicate real flight conditions. However, the observed differences in glucose levels and horizontal jump performance underline specific areas where real combat flight may impose unique demands.

These findings suggest that flight simulators are effective tools for replicating many of the psychophysiological demands of combat aviation, while also identifying areas where real combat conditions elicit distinct responses. This information is critical for optimizing training protocols and ensuring pilots are adequately prepared for operational demands.

Table 1: Acute effects of real and simulated combat flight on metabolic, respiratory and physical fitness variables

	Variables	Baseline Mean (SD)	Post Mean (SD)	Baseline vs post measure		Acute effects of a real vs a simulated mission	
				p-value	Effect Size	p-value	Effect Size
Real flight	Blood oxygen saturation (%)	98.58 (0.51)	98.00 (0.74)	.100	0.475	.476	0.205
Simulated flight		98.08 (0.67)	98.08 (0.67)	.527	0.182		
Real flight	Lactate (mmol/l)	1.92 (0.78)	2.86 (3.04)	.367	0.261	.790	0.077
Simulated flight		2.62 (1.78)	3.25 (2.97)	.533	0.180		
Real flight	Glucose (mg/dl)	96.42 (9.57)	96.25 (8.61)	.844	0.056	.084	0.498
Simulated flight		102.75 (14.04)	92.50 (4.74)	.021*	0.668		
Real flight	Cortisol (µg/dl)	9.70 (5.78)	7.56 (6.30)	.158	0.408	.445	0.220
Simulated flight		6.30 (4.83)	6.87 (7.01)	.386	0.250		
Real flight	Urine color (a.u.)	3.75 (1.71)	3.17 (0.94)	.176	0.391	.887	0.044
Simulated flight		3.08 (1.08)	2.58 (1.44)	.092	0.486		
Real flight	Fev1 (l)	5.11 (1.19)	4.81 (0.66)	.450	0.218	.142	0.424
Simulated flight		4.83 (0.68)	4.85 (0.65)	.123	0.445		
Real flight	FER25 (l)	3.92 (0.61)	4.08 (0.44)	.308	0.294	.722	0.103
Simulated flight		4.13 (0.64)	4.16 (0.75)	.260	0.324		
Real flight	FEF75 (l)	10.10 (1.89)	9.72 (2.07)	.477	0.205	1.000	<0.001
Simulated flight		9.98 (1.91)	9.27 (1.99)	.678	0.120		
Real flight	Handgrip (N)	52.62 (6.08)	51.92 (7.43)	.759	0.088	.386	0.250
Simulated flight		50.62 (7.23)	51.09 (5.47)	.858	0.051		
Real flight	Horizontal jump (cm)	141.33 (11.10)	147.42 (12.99)	.004*	0.839	.878	0.044
Simulated flight		137.42 (9.10)	144.09 (10.32)	.055	0.553		

**p-value <0.05*

DISCUSSION

Authors should discuss the results and how they can be interpreted from the perspective of previous studies and of the working hypotheses. The findings and their implications should be discussed in the broadest context possible.

Future research directions may also be highlighted.

This study aimed to analyze the acute psychophysiological effects of simulated and real combat flights in military pilots. The findings emphasize the utility of flight simulators for training purposes, as no significant differences were observed in most physiological and metabolic variables between simulated and real combat flights. These results align with previous research demonstrating that modern simulators effectively replicate many of the stressors encountered in real-world conditions, such as mental workload and physical demands while avoiding the risks associated with live operations [13,14,15]. The high fidelity of modern simulators in recreating operational environments supports their role as indispensable tools in pilot training.

Despite the overall similarity in physiological responses, certain differences were evident, providing nuanced insights into the unique demands of real combat flights. A significant improvement in horizontal jump performance following real flights was observed, suggesting that real combat maneuvers may elicit greater neuromuscular activation compared to simulated conditions. This response could be linked to the heightened cortical arousal and increased recruitment of fast-twitch muscle fibers required to cope with the physical and cognitive demands of real flight maneuvers. Similar findings have been reported in high-intensity military tasks, such as close-quarter combat and parachute jumps, where lower body strength improves due to acute neuromuscular adaptations to high-stress conditions [16,17,18]. These findings reinforce the hypothesis that real-world stressors induce unique physiological responses that are challenging to replicate entirely in simulated environments.

Interestingly, no significant changes were detected in handgrip strength, highlighting the distinct demands placed on upper body fine motor skills in piloting. Unlike lower body strength, which benefits from gross motor activation, piloting requires sustained precision and control over joystick or yoke movements, which rely on fine motor skills rather than maximal force. Previous research has similarly noted that tasks involving fine motor coordination are less affected by acute fatigue compared to those demanding gross motor output [19,20,21]. These results suggest that while simulators effectively mimic many neuromuscular demands, they may not fully capture the precise motor control required during real flight operations.

The absence of significant changes in blood lactate levels following real flights contrasts with findings in other high-stress combat scenarios, where anaerobic metabolism typically increases due to intense physical exertion [22,23]. This discrepancy may be attributed to the effects of G-forces during real flights, which redistribute blood flow, potentially reducing capillary perfusion at peripheral sampling sites. Simulated flights, lacking such mechanical stressors, exhibited lactate levels closer to the anaerobic threshold, further supporting the influence of G-forces on metabolic responses [24,25,26]. Research on the physiological effects of G-forces in combat aviation highlights their role in altering cardiovascular and metabolic regulation, with implications for pilot performance and endurance [27,28].

Respiratory function, as assessed by spirometry and blood oxygen saturation, showed no significant differences between simulated and real flights. The stability of these variables suggests that the participants' high level of operational experience and training enabled them to maintain respiratory efficiency across both conditions. Previous studies have identified respiratory fatigue as more prevalent among less experienced pilots or during extended operations [29,30]. The lack of observed respiratory impairments in this study underscores the resilience of experienced pilots. However, the reliance on spirometry alone may have limited the scope of respiratory assessments. Advanced techniques such as wearable strain gauge sensors or optoelectronic plethysmography could provide a more detailed understanding of respiratory patterns during flight [31,32].

Cortisol levels remained stable across both flight conditions, a finding that may reflect the effects of habituation associated with extensive operational experience. High-stress environments often elicit significant cortisol responses in less experienced individuals, but research has shown that habituation to stress reduces these responses over time in seasoned personnel [33]. This phenomenon is consistent with studies in other military contexts, where experienced individuals exhibit attenuated psychophysiological responses to acute stressors [34]. The stability of cortisol levels in this study further emphasizes the importance of experience in mitigating stress responses during high-pressure scenarios.

Hydration profiles, assessed through urine colorimetry, did not differ significantly between simulated and real flights. However, the hydration levels observed were close to dehydration thresholds, highlighting the need for improved pre-flight hydration strategies. Dehydration has been shown to impair both physical and cognitive performance, particularly in high-stress environments such as combat aviation [35,36,37]. The use of urine color charts for hydration monitoring has been validated in clinical and operational settings, offering a practical tool for maintaining optimal hydration status among pilots [38]. Addressing hydration deficits could enhance both safety and performance during flight operations.

The results of this study contribute to the growing body of literature emphasizing the effectiveness of flight simulators in replicating the majority of psychophysiological demands associated with real combat flights. However, the observed differences in neuromuscular and metabolic responses highlight specific areas where real flight conditions impose distinct challenges that simulators may not fully replicate. For instance, while simulators effectively mimic the mental workload and basic physiological demands of combat aviation, they may not accurately replicate the physical effects of G-forces or the fine motor requirements of real piloting.

These findings have important implications for the design and implementation of simulation-based training programs. By identifying the limitations of current simulators, training protocols can be refined to better prepare pilots for the unique demands of real combat scenarios. For example, incorporating supplementary training exercises that target neuromuscular activation and motor coordination could address the gaps identified in this study. Additionally, integrating advanced physiological monitoring tools, such as portable biosensors and electroencephalography, could enhance the precision and effectiveness of simulation-based training [39,40,41].

Limitations of the study

This study has several limitations that should be considered when interpreting the results. First, the relatively small sample size (n = 12) limits the generalizability of the findings, particularly given the elite status of the participants as experienced military pilots. Access to larger samples in similar operational contexts remains a challenge, but it would enhance the robustness of the conclusions. Second, the study did not control for gender differences, which may introduce variability in psychophysiological responses. Given the increasing presence of female pilots in military aviation, future studies should aim to include a gender-balanced sample.

Another limitation is the reliance on conventional physiological and metabolic measures, such as spirometry and blood lactate levels, which may not fully capture the complexity of pilot responses during flight. The lack of advanced monitoring techniques, such as electroencephalography (EEG) or respiratory inductive plethysmography, restricts the scope of insights into neuromuscular and respiratory dynamics. Additionally, the study did not evaluate psychological measures such as perceived exertion, stress, or workload, which are critical components of the psychophysiological response in high-stress environments.

Finally, while the study focused on acute effects, it did not assess the cumulative impact of repeated exposure to simulated and real flight conditions. Chronic stress and its potential long-term effects on pilot health and performance warrant further exploration.

Practical applications

Our research on the effects of experience on the findings of this study has direct implications for improving pilot training and operational readiness. The demonstrated effectiveness of flight simulators in replicating many psychophysiological demands of real combat flights supports their continued use as a safe, cost-effective, and practical training tool. Simulators allow pilots to acclimate to combat stressors without exposure to the risks associated with live operations, such as physical injury or equipment failure. These insights reinforce the value of simulators in enhancing pilot preparedness, particularly during the early phases of training.

The observed differences in neuromuscular activation and metabolic responses between real and simulated flights highlight areas where simulation-based training can be refined. Incorporating supplementary neuromuscular exercises, such as lower body strength training, may enhance physical preparedness for real combat scenarios. Additionally, addressing hydration deficits through pre-flight hydration protocols could mitigate the risk of dehydration-related performance decrements.

Moreover, the study underscores the importance of tailoring training protocols to individual pilot characteristics, including experience level and physiological baseline. Advanced monitoring technologies, such as wearable biosensors, could be integrated into training programs to provide real-time feedback on physiological and psychological responses, enabling personalized training adjustments.

Future research lines

Future research should build upon the findings and limitations of this study by addressing several key areas. First, future studies should include larger sample sizes and greater diversity, particularly through the inclusion of female pilots. This approach would improve the generalizability of findings and allow for a deeper exploration of potential gender differences in psychophysiological responses. Additionally, investigations into the cumulative effects of repeated exposure to both simulated and real combat flight conditions are essential. These studies could provide valuable insights into the long-term impact of operational stressors on pilot health, performance, and resilience, areas that remain underexplored.

Advanced physiological and psychological monitoring tools should also be integrated into future research. Techniques such as electroencephalography (EEG), respiratory inductive plethysmography, and portable biosensors could offer a more comprehensive understanding of pilot responses. These tools would enable the assessment of critical parameters, including brain activity, detailed breathing dynamics, and stress biomarkers, allowing for a more nuanced analysis of the interaction between physiological and psychological stressors.

Incorporating psychological measures, such as perceived exertion, workload, stress, and fatigue, will also enhance future studies by providing a holistic view of pilot performance under stress. These measures would complement physiological data and help elucidate the interplay between mental and physical demands in combat aviation. Furthermore, comparing psychophysiological responses between novice and experienced pilots would yield valuable insights into how training and habituation influence operational readiness, offering opportunities to tailor training programs to the specific needs of pilots at different stages of their careers.

Another important area for future research involves enhancing the fidelity of flight simulators. Efforts should focus on better replicating the physical effects of G-forces and other unique stressors encountered during real combat flights. Advanced simulation technologies that integrate neuromuscular and metabolic stressors could bridge the gap between simulated and real flight conditions, thereby improving training effectiveness.

Hydration and nutritional strategies represent another critical avenue for investigation. Tailored interventions to optimize hydration status and metabolic recovery could significantly enhance pilot performance during combat scenarios. Research in this area would address a practical operational need and contribute to the development of evidence-based protocols to support pilot health and performance.

Finally, cross-operational comparisons should be conducted to broaden the scope of research. Investigating psychophysiological responses across different aviation contexts, such as helicopter pilots or unmanned aerial vehicle (UAV) operators, would provide a more comprehensive understanding of aviation-specific stressors and their management. These comparisons would also facilitate the identification of universal stressors and strategies applicable across various aviation roles, contributing to the overall advancement of the field.

CONCLUSION

The present study underscores the essential function of flight simulators within pilot training frameworks, particularly in their capacity to replicate a substantial portion of the psychophysiological demands encountered in actual combat aviation scenarios. Nevertheless, the discrepancies identified in neuromuscular activation patterns and metabolic responses indicate that simulators may fall short in fully emulating the intricate physiological challenges of real-world flight operations. Bridging these limitations through the integration of targeted training interventions and sophisticated monitoring methodologies has the potential to enhance pilot preparedness and physiological resilience, thereby contributing to improved performance and mission safety. These results highlight the necessity of ongoing research aimed at refining training protocols to ensure that pilots are effectively equipped to meet the complex requirements of contemporary aerial warfare.

Conflicts of interest and sources of funding

The authors declare no conflict of interest. No artificial intelligence automatically generated text was inserted in this manuscript, and no image was previously published in another journal or is under consideration of being published elsewhere. This research received no external funding.

Acknowledgments

This study has been made thanks to the contribution of the 3rd Wing located in the Talavera la Real Air Base (Badajoz) of the Spanish Air Force (Ministry of Defence) as well as the Department of Economy and Infrastructure of the Junta de Extremadura through the European Regional Development Fund. Abstract: Background Medical rescue transfer and handover in manned spaceflight is a critical component of space rescue operations, directly impacting the safety and well-being of astronauts. Objective This study aims to develop a comprehensive checklist for the medical rescue transfer and handover processes associated with manned spaceflight, thereby enhancing the efficiency of these procedures. Methods The checklist was designed and implemented during practical training sessions focused on manned space medical rescue. Participants were divided into two groups: one utilizing the checklist for transfer handover and another relying on verbal communication. Key metrics such as transfer time, quality of handover, and satisfaction scores were collected and analyzed for both groups. Results The group employing the checklist demonstrated significantly improved outcomes compared to the verbal group in terms of transfer time, quality of handover, and overall satisfaction scores ($P < 0.001$). Conclusion The implementation of checklist management has been shown to enhance both the efficiency and quality of transportation and handover processes, establishing a robust foundation for successfully executing manned space medical rescue missions.

Keywords: Manned Space Medical Rescue; Transfer; Handover; Checklist Management

INTRODUCTION

China's manned space program has advanced to the stage of conducting missions involving a space station, resulting in significantly extended durations for astronauts' stays. These missions are increasingly arduous and complex, which elevates the likelihood of accidental injuries and illnesses [1,2,3]. Space medical rescue is a critical component in ensuring astronaut safety and constitutes an essential aspect of manned space system engineering [4,5]. The efficiency and quality of transfer and handover during medical rescue directly impact the stability and prognosis of astronauts. Research indicates that standardized transfer handovers can reduce handover time, enhance accuracy and efficiency, and decrease the occurrence of adverse events. Checklist management has emerged as an effective strategy to mitigate errors arising from oversight; it offers advantages such as rapid comprehension, straightforward implementation, and precise handovers [6,7]. Currently, checklist management has been successfully employed in emergency evacuation and transfer protocols by foreign Marine Corps units, yielding positive outcomes in reducing adverse incidents while improving the quality of transfers and handovers [8].

This study aims to implement checklist management within nursing transfer processes during aerospace medical rescue training. A statistical analysis will be conducted on the time taken for these transfers, the quality achieved therein, as well as satisfaction levels among nursing staff compared with traditional oral handovers. This approach seeks to provide insights into methodologies for enhancing both the quality and efficiency of aerospace medical rescue operations alongside nursing transfers and handovers.

One population that has been identified as vulnerable to acquiring HIV infection is military personnel, due to frequently reported high-risk sexual behaviour [9,10] or to their high mobility and exposure to biologically foreign environments [11,12].

By convening a panel of eight experienced experts in the field of space medicine, we developed a comprehensive checklist for manned space rescue, transfer, and handover procedures. In designing the content, we prioritized the timeliness of first aid interventions prior to astronauts exiting their cabin. This checklist encompasses critical information including the arrival time of medical rescue personnel, the timing of astronaut cabin egress, on-site emergency treatment duration, astronaut evacuation timing, as well as vital signs monitoring and condition changes throughout the evacuation process [8]. As illustrated in Table 1, the handover list is categorized into four dimensions comprising fifteen items:

(1) Basic Information: This section includes data such as astronaut identification number, gender, age, exit time from the cabin, and entry time into the medical transport vehicle.

(2) Preparation Before Transport: This dimension covers essential vital signs of astronauts prior to transport along with safety measures for astronauts themselves; it also addresses preparations by medical staff and necessary equipment.

(3) Observation During Transport: Key observations during transportation include monitoring astronauts' vital signs—such as consciousness level, blood pressure readings, heart rate fluctuations, oxygen saturation levels—and noting any sudden changes in their condition.

(4) Transfer and Handover: The final category consists of data regarding consciousness levels and vital signs at transfer points; skin status assessments; past medical history including allergies; venous access details; artificial airway management; and medications administered during transit.

The signature section was duly signed off by both nursing staff involved in pre-cabin treatment and transport as well as receiving nursing personnel at the destination hospital. Additionally, precise records were maintained detailing each step of an astronaut's transfer to a ward down to minute-level accuracy. The transfer handover documentation exists in duplicate copies that are stored separately to serve as formal handover references.

2. Training of transfer handover list

After the completion of the design for the transfer and handover checklist, nursing staff training was conducted by the organizers in accordance with expert consensus on astronaut treatment before the re-entry module of the landing site of space station mission[4]. This training also adhered to the Standard Operating Procedure (SOP) for emergency medical care for astronauts[9,10,11], as well as operational specifications pertaining to medical care and support during space station missions[12,13]. Methods such as group discussions and scenario simulation demonstrations were employed to elucidate each item on the checklist systematically. The effectiveness of this training was assessed through on-site questioning, ensuring that participants comprehensively understood each item and minimizing potential errors in documentation.

3. Group study on the transfer handover list

To implement the transfer and handover checklist in manned space medical rescue training, a study was conducted with two groups: a control group utilizing traditional oral handover methods and an experimental group employing the checklist handover approach. Each group consisted of 15 participants. The metrics evaluated included transfer preparation time, transfer handover time, and total transfer time.

Transfer preparation time refers to the duration required for the simulated astronaut to enter the transport carrier, during which the medical team counts personnel, consumables, and equipment while confirming both the condition of the injured individual and the status of all equipment. Transfer and handover time encompasses the period needed for the simulated astronaut to exit from the transport carrier and be transported to the astronaut ward. This phase includes transferring essential information such as basic details, vital signs, level of consciousness, and any changes in condition between pre-cabin rescue nursing staff and posterior support hospital nursing staff.Total transit time is defined as the cumulative sum of both transit preparation time and transit handover time.

4.Evaluation

The handover process with the posterior branch hospital was systematically evaluated by the training team leader during each transfer. The quality of handover for both the experimental group and the control group was assessed based on three key components: preparation prior to transfer, the actual transfer and handover process, and comprehension of the patient's disease status. Each component was assigned a score ranging from 1 to 3 points, where 3 points indicated excellent performance, 2 points denoted good performance, and 1 point represented fair performance.

Concurrently, a satisfaction questionnaire was distributed to nursing staff at the backward branch hospital to gauge their satisfaction regarding the transfer and handover process across six dimensions: vital signs monitoring, level of consciousness, changes in condition, venous access management along with other pipelines, medication administration, and skin conditions. Each aspect received a score between 1 (minimum) and 10 (maximum).

5.Statistical analysis

All data were analyzed using IBM SPSS Statistics 24 . Measurement data that conformed to a normal distribution were presented as mean(M) ± standard(SD) deviation. Count data were expressed in terms of frequency (percentage). The comparison of normally distributed measurement data between the two groups was conducted using an independent samples t-test.

RESULTS

1. Transit time

The transfer time was significantly reduced in the experimental group compared to the control group. In the experimental group, the transfer preparation time averaged 13.27±1.10 minutes, while the transfer handover time was 9.73±1.67 minutes, resulting in a total transfer time of 23.00±1.89 minutes. Conversely, in the control group, the average transfer preparation time was 18.13±2.07 minutes and the transfer handover time was 14.80±1.97 minutes, leading to a total transport time of 32.93±2.84 minutes. The difference between these two groups was statistically significant (P <0.001). Detailed results are presented in Table 2.

Table 2: Comparison of transit times in different groups

Groups	Number	Transit Preparation Time (min)	Transfer Handover Time (min)	Total Transit Time (min)
Control group	15	18.13±2.07	14.80±1.97	32.93±2.84
Experimental group	15	13.27±1.10	9.73±1.67	23.00±1.89
T		10.21	13.65	15.1
P		<0.001	<0.001	<0.001

2. Quality of transfer handover

The scores of the experimental group surpassed those of the control group across three dimensions: preparation prior to transfer, the transfer and handover process, and mastery of disease status. As illustrated in Table 3, the mean scores for preparation before transfer, transfer handover process, and mastery of disease status in the experimental group were 3.00±0.00, 2.53±0.51, and 2.60±0.50, respectively. In contrast, the corresponding scores for the control group were 2.40±0.13, 1.67±0.49, and 1.60±0.63. The differences between these two groups were statistically significant (P < 0.001).

Table 3: The quality of transfer handover was compared in different groups

Groups	Number	Prepare Before Transfer	Transfer Handover Process	Mastery of Disease Status
Control group	15	2.40±0.13	1.67±0.49	1.60±0.63
Experimental group	15	3.00±0.00	2.53±0.51	2.60±0.50
T		-4.58	-6.5	-5.12
P		<0.001	<0.001	<0.001

3.Satisfaction

Table 4 presents the satisfaction survey scores of medical staff at the posterior branch hospital. The satisfaction scores for the experimental group regarding vital signs, state of consciousness, condition changes, venous access and various pipelines, medication, and skin conditions are as follows: 9.83 ± 0.27, 9.41 ± 0.37, 9.56 ± 0.38, 9.41 ± 0.37, 9.66 ± 0.38, and 9.67 ± 0.38 respectively. In contrast, the control group's satisfaction scores in these same categories were: vital signs (8.73 ± 0.45), state of consciousness (8.57 ± 0.39), disease changes (8.75), venous access and each pipeline (8.63 ± 0.46), medication (8.79 ± 0 .41), and skin conditions (8 .59± 0 .50). The results indicate that the experimental group exhibited significantly higher satisfaction levels compared to the control group (P < 0 .001).

Table4: Comparison of disability among soldiers with different reasons

Groups	Number	Vital Signs	State of Consciousness	Changes in Condition	Pipe Line	Medication	Skin
Control group	15	8.73±0.45	8.57±0.39	8.75±0.41	8.63±0.46	8.79±0.29	8.59±0.50
Experimental group	15	9.83±0.27	9.41±0.37	9.56±0.38	9.41±0.37	9.66±0.38	9.67±0.38
T		-9.39	-8.82	-8.84	-6.24	-8.56	-7.63
P		<0.01	<0.01	<0.01	<0.01	<0.01	<0.01

DISCUSSION

To ensure the life and health of astronauts is fundamental to manned space projects. A review of the history of manned space flight worldwide reveals a number of accidents that have resulted in significant losses. In the United States, there have been 19 incidents and failures during manned space flights, leading to 18 fatalities. The former Soviet Union conducted numerous manned space missions, which also resulted in injuries among astronauts, including six deaths [14,15]. To date, all of China's manned space missions have been successfully completed without any serious injuries. As our country embarks on a new phase with its space station program, the frequency of manned launch missions is increasing, while records for in-orbit flight durations continue to be extended. This rise introduces unforeseen factors and maintains an ongoing risk of accidental injury to astronauts. In the event of such an accident, medical rescue serves as the final safeguard for astronaut safety.

The transfer and handover process is a critical component of aerospace medical rescue, significantly influencing the prognosis of injured individuals and patients. The occurrence of adverse events during transfer and handover is closely associated with various factors, including equipment issues, patient conditions, communication barriers, and other challenges faced by medical personnel [16,17]. Implementing an appropriate transfer and handover checklist can enhance communication efficiency among medical staff, enabling them to quickly and effectively comprehend the patient's condition while minimizing the risk of overlooking essential information. This ultimately ensures the safety of patients during their transfer [18,19].

By utilizing a standardized checklist for transfer handovers that delineates key points and critical content in written form, a unified standard is established. This approach improves both the accuracy and efficiency of the transfer process while preventing omissions of vital items. Consequently, it facilitates evidence-based practices in transfer handovers and safeguards patient safety throughout this procedure [20]. Research indicates that employing a checklist for handovers can reduce the incidence of adverse events during transfers from 13.8% to 5.4%, thereby significantly enhancing both quality and efficiency in these processes [21].

Checklist management was implemented in the transfer and handover process of aerospace medical rescue training. Utilizing a transfer and handover checklist, each item was marked off systematically, resulting in a rapid and concise documentation process with accurate and clear recorded content. The critical links that are often overlooked during handovers were consolidated into a standardized format to mitigate the risks associated with oral communication, thereby reducing the likelihood of omissions or repetitions. This approach not only saves time during transfers but also ensures that medical personnel at receiving hospitals have comprehensive access to vital signs and overall injury assessments of simulated casualties throughout the entire evacuation process [22]. The findings from this study indicated that the checklist-based handover group (experimental group) outperformed the oral handover group (control group) significantly across two evaluation metrics: transfer handover time and quality. Furthermore, medical staff at the receiving hospital expressed markedly higher satisfaction regarding six key aspects of the transfer process compared to their counterparts in the oral handover group (control group).

The practice of aerospace medical rescue training has demonstrated that checklist management offers several advantages:

(1) Ensuring the accuracy of transfer and handover information. Traditional oral handovers often suffer from inaccuracies in information transmission, ambiguity regarding key content, omissions of critical disease data, and sometimes deficiencies in the objectivity, accuracy, and completeness of the conveyed information. These unclear handovers and existing shortcomings directly impact the quality of care following transfer. By utilizing a tabular format, a nursing transfer and handover checklist can effectively reflect the basic situation and condition of simulated astronauts in a simple, comprehensive, and intuitive manner. This checklist provides complete information—including vital signs, illness details, rescue efforts, and nursing considerations—for medical personnel at posterior support hospitals. It serves as both a reference point for handover tasks and contributes to making the process more standardized and evidence-based.

(2) Improving the quality and efficiency of transfers and handovers. The checklist facilitates an item-by-item review according to its contents during handover sessions; this approach significantly reduces omissions related to key content or data due to limitations in energy levels or memory capacity among medical staff—factors exacerbated by misunderstandings or time constraints. Consequently, it shortens overall handover duration while substantially enhancing its quality. Research findings indicate that groups utilizing checklists for handovers performed significantly better than those relying on oral communication concerning both transfer times and overall quality of transfers. Following implementation of checklist-based procedures for handing over responsibilities, there is clear evidence that both efficiency and quality are markedly improved while ensuring safety and timeliness throughout the process.

(3) To ensure the safety of astronaut transportation, space medical rescue is critical to both the life and safety of astronauts as well as the overall success or failure of the mission. In the event that an astronaut sustains an accidental injury, there are heightened risks associated with the transfer process. The implementation of a checklist handover serves as a safe nursing practice designed to facilitate effective communication before, during, and after the transfer based on a predetermined transfer handover list [23]. The self-designed transfer handover checklist plays a vital role in conducting risk assessments prior to transfer, thoroughly evaluating timing considerations, and emphasizing careful monitoring of conditions along with emergency interventions throughout the transfer process. Upon safely reaching their destination for transfer, this checklist is utilized once more to convey essential information

regarding vital signs, consciousness levels, venous access status, various drainage tubes in place, medication administered, and any changes in condition experienced by the astronauts. This systematic approach proves beneficial for medical personnel at receiving facilities by enabling them to swiftly assess conditions and execute necessary procedures effectively.

CONCLUSION

With the successful completion of the inaugural in-orbit rotation involving the astronaut teams of Shenzhou 14 and Shenzhou 15, China's space station has transitioned into a long-term operational mode. Consequently, space medical rescue and support missions will now be conducted under standard working conditions. This study demonstrates that effective checklist management can enhance both the efficiency and quality of the transfer handover process. The objective of this approach is to normalize, standardize, and systematize the procedures for space medical rescue transfers and handovers, thereby establishing a robust foundation for the successful execution of astronaut medical support and rescue operations.

Conflicts of interest and sources of funding

The authors declare no conflict of interest and this research received no external funding.

Authors' contribution

The initial draft was prepared and revised by JL, while GH, PS, XG, and LD contributed to the collection of information and the preparation of the dataset. YW further refined the analyses and provided essential support for the manuscript. LS and YT supervised all aspects of the study, including the design of the data analysis plan, oversight of the data analysis process, validation of results, and writing of the manuscript based on the first draft. All authors participated in reviewing and finalizing the manuscript; furthermore, all interested parties have read and approved it.

Ethics approval and consent to participate

This study does not consider pertinent ethical issues related to individuals.

Abstract: Background and Aim: Digital skills of healthcare professionals are recognized as critical for the successful digital transformation of healthcare. The present study aims to examine the relationship between the digital skills of healthcare professionals and the organizational structures of hospitals. Methods: In this cross-sectional study, using the convenience sampling method, 857 healthcare professionals, working in Greek military and civilian hospitals, voluntarily participated. Data were collected between July and November 2021 through a structured questionnaire, based on the Digital Competence framework. Digital skills were categorized into five subscales: information, communication, content creation, problem solving, and safety skills. Statistical analysis was performed with SPSS 26.0, with p-values <0.05 considered statistically significant. Results: Cronbach's alpha values for all subscales were (α)>0.8, indicating high reliability. Younger participants showed higher scores (p<0.001). The mean scores for information, communication, content creation, problem solving and safety skills in military hospitals were calculated as 52.1 (SD=32.3), 50.6 (SD=31.8), 48.4 (SD=33.3), 49.8 (SD =30.8) and 52.8 (SD=34.1) respectively, while in civilian hospitals they were calculated as 45.1 (SD=32.2), 44.5 (SD=29.5), 41.8 (SD=32.4), 41.5 (SD=30.8) and 47.1 (SD=34.5) respectively. Conclusions: Healthcare professionals in military hospitals exhibit higher digital competence compared to their counterparts in civilian hospitals. Identifying the organizational factors that promote greater digital competence among healthcare professionals provides essential information to policymakers and healthcare managers for implementing targeted organizational improvements.

Keywords: Digital skills, Healthcare professionals, Military hospitals, Digital Competence framework

INTRODUCTION

The management of competencies and skills in the healthcare sector has drawn significant attention from international organizations, recognizing that a well-trained workforce is essential for ensuring patient safety and delivering high-quality care [1,2]. In alignment with the continuous advancements in medical technology, the necessity for healthcare professionals to develop new skills has become increasingly urgent [3,4]. This need was starkly highlighted during the recent COVID-19 pandemic, where the heightened digital demands of healthcare services underscored the importance of sufficient digital capabilities [5,6].

In particular, digital skills are deemed critical not only for the effective management of healthcare organizations but also for medical diagnosis, treatment monitoring, patient care, and decision-making processes [7,8]. Within the healthcare domain, digital competence encompasses knowledge of digital literacy and technology as essential tools for the patient-centered provision of quality healthcare services. It reflects the dynamic interaction between healthcare professionals, patients, and colleagues, as well as the drive to acquire professional expertise in digital technology [9,10].

It is widely recognized that digital competencies are essential for the effective integration of health technologies into routine clinical practice. Numerous processes are now carried out digitally, such as patient monitoring, where electronic health records and vital sign monitoring systems enable doctors and nurses to track patient status in real time. Material procurement is also facilitated through electronic systems, enhancing both accuracy and efficiency. Furthermore, telemedicine plays a pivotal role, particularly in military hospitals, by enabling the delivery of healthcare services to remote areas and military bases. Digital tools further support decision-making by allowing healthcare professionals to analyze data and make evidence-based decisions more efficiently [3,11,12].

In Greece, military hospitals offer more structured training programs for digital skills, supported by military frameworks that emphasize continuous professional development of their personnel. These programs encompass modules on the management of digital tools, telemedicine, and electronic patient record systems, reflecting the military's long-standing tradition of structured training and lifelong education. Additionally, military healthcare professionals are often encouraged to engage in e-learning programs to further enhance their expertise in healthcare technologies.

Conversely, in public hospitals, training programs for digital skills vary depending on the institution and the extent of technological integration. Significant advancements have been observed in large hospitals that have adopted electronic medical records; however, training opportunities remain limited due to resource constraints and time pressures. Healthcare professionals, including nurses and doctors, typically receive training through Ministry of Health initiatives or European-funded programs such as eHealth and Horizon 2020 [9,10].

Despite extensive research on digital skills, a literature review from the past decade indicates a scarcity of studies that examine the digital competencies of healthcare professionals within a specific and well-defined conceptual framework. One such framework is the European Digital Competence (DigComp) Framework, created by the European Union as a common umbrella of digital competences for its citizens, which defines digital competence domains, indicators for each domain, competence levels, examples of knowledge, skills, and attitudes, as well as examples of application [13]. Moreover, limited research has explored the associations between digital skills and the organizational work environment. To the best of our knowledge, no prior studies have investigated differences in this domain between military and civilian healthcare professionals.

Therefore, the objective of this paper is to address this research gap by examining the relationship between digital skills of healthcare professionals and the organizational structures of their work environments. We aim to contribute evidence on the organizational factors influencing healthcare professionals' digital competencies, which can inform policymakers and healthcare managers' efforts to implement targeted organizational improvements.

MATERIALS AND METHODS

Study Design

A cross-sectional survey utilizing a descriptive study design was conducted based on prior research, which demonstrated that the Digital Competence Indicator tool is a reliable and valid measurement scale applicable to Greek doctors and nurses [14]. The study addressed two primary research questions: (1) How are healthcare professionals' digital skills assessed? and (2) Are there differences in the digital skills of healthcare professionals between military and civilian hospitals?

The present study was conducted as part of the research activities of the Department of Nursing at the Hellenic Mediterranean University and received ethical approval from the Review Committee (Protocol No.: 4634/29-03-2021). Additionally, the necessary permissions were obtained from the Scientific Committees of all participating hospitals (Protocol No.: 5584/1973/26-06-2021). Data were collected using a self-assessment questionnaire, with the principal investigator maintaining sole access to the collected data. Participation was entirely voluntary, and all participants were informed both verbally and via an information/consent form that completing and returning the questionnaire constituted their consent to participate in the study. The information/consent form was approved by the above Scientific Committees. The research adhered strictly to the European Union's General Data Protection Regulation, ensuring full compliance with personal data protection standards.

Participants and settings

A convenience sample of doctors and registered nurses was selected from seven tertiary care hospitals in Greece. This particular sampling method was preferred because it offers time and cost savings, ease of access, and an abundance of qualitative data. However, it carries the risk of bias and systematic errors, and therefore, research findings cannot be accurately generalized beyond the study sample. The selection of hospitals was based on the diversity of organizational structures between military and civilian institutions, as well as the aim of achieving a large sample size. The study population size was calculated using a 95% confidence interval and a 5% margin of error, ensuring that the final sample accurately represented healthcare professionals in Greek hospitals. The target sample size was N>800. A total of 1207 questionnaires were distributed, and 876 were collected, of which 19 were invalid due to incomplete responses. Thus, the study population is N=857.

The inclusion criteria for participation were employment in either a military or civilian hospital, professional status as a doctor or nurse, and, for nurses, registration as per the European Qualifications Framework (EQF). The distribution of questionnaires was proportional to the size of each hospital, based on the number of medical and nursing staff within the institutions. Data collection occurred during staff meetings, where participants from various work positions within the hospitals were approached, provided with explanations of the study objectives, and given clarifications on completing the questionnaire. Data collection was conducted between July and November 2021.

Research tool

Data were collected using a validated 37-item paper-based questionnaire. It is built on the European DigComp Framework, which comprehensively defines the elements of digital competence as a combination of skills, abilities and attitudes essential for incorporating data processing into the professional careers of healthcare providers [13,15].

The questionnaire consisted of two parts. The first part captured demographic characteristics, including gender, age, educational level, profession, specialty, hospital type, professional experience, administrative responsibilities, and possession of digital skills certification. The second part assessed 26 digital skills, organized into five competency domains (subscales): information, communication, content creation, problem-solving, and safety skills (Table 1).

Table 1: Competence area and digital skills of the questionnaire. Adapted from the European Commission's DigComp framework [13]

Competence Area	Digital Skills
Information Skills	1. Finding information about goods and services
	2. Obtaining information from public authority websites
	3. Reading or downloading online news/newspapers/news magazines
	4. Copying or moving a file or folder
	5. Seeking health-related information
Communication Skills	6. Sending/receiving emails
	7. Telephoning over the internet/video calls (via webcam) over the internet
	8. Participating in social networks
	9. Posting messages to chat sites
	10. Uploading self-created content to any website to be shared
Content Creation Skills	11. Creating websites or blogs
	12. Writing a computer programme using a specialized programming language
	13. Using copy and paste tools to duplicate or move information within a document
	14. Creating electronic presentations with presentation software (e.g., slides), including e.g., images, sound, video, or charts
	15. Using basic arithmetic formulae to add, subtract, multiply, or divide figures in a spreadsheet
Problem-Solving Skills	16. Connecting and installing new devices
	17. Installing a new or replacing an old operating system
	18. Modifying or verifying the configuration parameters of software applications
	19. Doing an online course
	20. Buying or ordering goods or services for private use (last 12 months) over the internet
	21. Selling online
	22. Job search or sending an application
	23. Internet banking
	24. Making an appointment with a practitioner via a website
Safety Skills	25. Using any kind of IT security software or tool (anti-virus, anti-spam, firewall, etc.) in order to protect private computers and data
	26. Updating one or more security products at least occasionally

Subscale values were calculated on a scale ranging from 0 to 100, with scores approaching 0 reflecting a more negative evaluation of the variable and scores approaching 100 reflecting a more positive assessment.

The questionnaire provided a concise yet compelling assessment of the Information Technology (IT) skills of hospital doctors and nurses. Designed for ease of use and brevity, it was particularly suitable for hospital settings often characterized by high workloads and limited time for activities outside core medical and nursing responsibilities. Participants rated the extent of their computer usage for each activity on a five-point Likert scale, ranging from 1 ("not at all") to 5 ("very much").

Data Analysis

Statistical analysis was performed using SPSS (Statistical Package for Social Sciences) version 26.0. Continuous variables were expressed as mean ± standard deviation (SD) and categorical variables were presented as absolute numbers (n) and percentages (n%). The normality of variables was assessed using the Shapiro-Wilks test, alongside graphical methods such as the Normal Q-Q plot, Detrended Normal Q-Q plot, and Box Plot. For all statistical tests, differences were considered significant at $p < 0.05$. Effect sizes weren't reported. The independent t-test was employed to compare the means of two groups, while one-way analysis of variance (ANOVA) was used for comparisons involving more than two group means.

RESULTS

Participant's characteristics

The study population comprised 857 Greek healthcare professionals employed across seven tertiary care hospitals. The results indicate that 538 participants (62.8%) were female, while 319 (37.2%) were male, with a mean age of 39.7 years (SD = 10.0). Of the total, 657 participants worked in military hospitals, while 200 worked in civilian hospitals. Indicatively, it is reported that the number of military doctors and nurses in hospitals, at the present time, amounts to approximately 1,700 people.

Specifically, among the military hospitals, 384 participants were from the 251 Hellenic Air Force General Hospital, 110 from the 401 General Military Hospital of Athens, 66 from the Athens Naval Hospital, and 97 from the General Military Training Hospital. Among civilian hospitals, 82 participants were from the Sismanoglio General Hospital of Attika, 51 from the Asklepieio Voulas General Hospital, and 67 from the Henry Dunant Hospital Center.

The majority of participants were registered nurses (70.2%), with doctors comprising 29.8% of the sample. Considering the nature of the study population, where nurses outnumber doctors by more than twice, the preponderance of the female gender can be explained by the fact that the nursing profession in Greece has traditionally been considered female-dominated for many years. The average professional experience was estimated at 15.3 years. Regarding educational levels, 528 participants (61.6%) held a Bachelor of Science (BSc) degree, 275 (32.1%) had also completed a Master's degree, and 54 (6.3%) held a PhD degree. Examining the level of education by profession, doctors have a higher proportion of PhD holders (5.4%) than nurses (0.9%). Conversely, nurses have a higher percentage of master's degree holders (22.8%) than doctors (9.3%). The demographic characteristics of the study population are summarized in Table 2.

Table 2: Demographic characteristics of participants (N = 857).

		Hospital				**Total**		
		Civilian hospital		***Military hospital***				
		N	N %	N	N %	N	N %	p-value
Age (years)*		40.6 (9.9)		39.4 (10)		39.7 (10)		0.143
Gender	Female	134	67.0%	404	61.5%	538	62.8%	0.158
	Male	66	33.0%	253	38.5%	319	37.2%	
Educational level	BSc	136	68.0%	392	59.7%	528	61.6%	0.092
	MSc	52	26.0%	223	33.9%	275	32.1%	
	PhD	12	6.0%	42	6.4%	54	6.3%	
Profession	Medical Doctor	53	26.5%	202	30.7%	255	29.8%	0.250
	Registered Nurse	147	73.5%	455	69.3%	602	70.2%	

**Note. Age expressed as mean (standard deviation)*

Digital Skills

Regarding digital skills, the results are overall. The mean scores of all digital skills subscales indicate an average level and are as follows: information skills, 52.1 (SD = 32.3); communication skills, 50.6 (SD = 31.8); content creation skills, 48.4 (SD = 33.3); problem-solving skills, 49.8 (SD = 30.8); and safety skills, 52.8 (SD = 34.1). Median scores, interquartile ranges (IQR), and p-values of the above subscales are presented in Table 3.

The reliability of the subscales was confirmed, with Cronbach's alpha values indicating high internal consistency: information skills (5 items; $\alpha = 0.95$), communication skills (5 items; $\alpha = 0.95$), content creation skills (5 items; $\alpha = 0.95$), problem-solving skills (9 items; $\alpha = 0.97$) and safety skills (2 items; $\alpha = 0.92$). Cronbach's alpha was calculated by group. It is worth noting that the high Cronbach's alpha values (>0.9) observed in the study results are likely due to the narrowness of the aspect structure of the measurements' tool subscales. However, the measurement scale was taken as an existing structure from the European DigComp Framework and was not developed by the researchers. Future survey to explore the factor structure by removing some potentially redundant items or adding new ones is a challenge for the present investigators.

Table 3: Median scores, IQR, and p-values of subscales (information skills, communication skills, content creation skills, problem-solving skills, safety skills) per type of hospital

		Hospital		
		Civilian hospital	**Military hospital**	**Total**
Information skills	Median	45.00	60.00	55.00
	IQR	63.75	60.00	60.00
	p-value	<0.001		
Communication skills	Median	40.00	55.00	50.00
	IQR	50.00	65.00	60.00
	p-value	0.002		
Content creation skills	Median	40.00	50.00	50.00
	IQR	60.00	67.50	65.00
	p-value	0.001		
Problem-solving skills	Median	30.60	52.80	50.00
	IQR	58.30	52.80	55.60
	p-value	<0.001		
Safety skills	Median	37.50	62.50	62.50
	IQR	71.88	62.50	62.50
	p-value	0.007		

The mean scores across all five subscales of the measurement tool were found to differ significantly between military and civilian hospitals. Specifically, the mean score for the "Information skills" subscale in military hospitals was M = 54.2 (SD = 32.1), compared to M = 45.1 (SD = 32.2) in civilian hospitals, with t(855) = -3.522, $p < 0.001$. For the "Communication skills" subscale, the mean score in military hospitals was M = 52.4 (SD = 32.3), while in civilian hospitals it was M = 44.5 (SD = 29.5), with t(855) = -3.088, p = 0.002.

Similarly, the "Content creation skills" subscale showed a mean score of M = 50.4 (SD = 33.3) in military hospitals versus M = 41.8 (SD = 32.4) in civilian hospitals, with t(855) = -3.236, p = 0.001. For "Problem-solving skills," the mean score in military hospitals was M = 52.4 (SD = 30.4), compared to M = 41.5 (SD = 30.8) in civilian hospitals, with t(855) = -4.395, $p < 0.001$. Lastly, the "Safety skills" subscale yielded a mean score of M = 54.6 (SD = 33.8) in military hospitals and M = 47.1 (SD = 34.5) in civilian hospitals, with t(855) = -2.740, p = 0.006.

The mean values (SD) of digital skills (information, communication, content creation, problem-solving, and safety skills) by hospital type are illustrated in Figure 1.

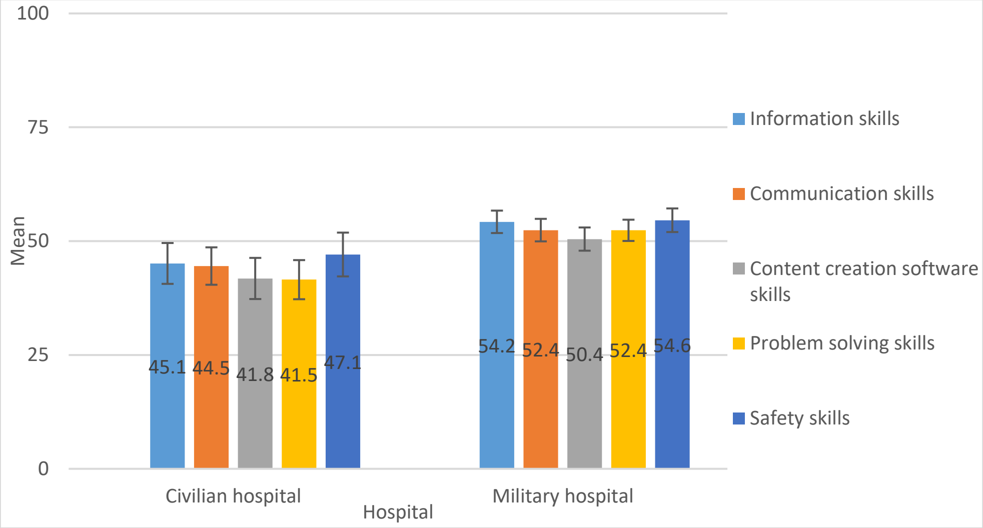
DISCUSSION

Based on the theoretical framework outlined, the findings of this study align with existing research emphasizing the growing importance of digital skills for healthcare professionals. Digital competence is essential not only for the effective delivery of healthcare services but also for ensuring patient safety and enhancing the overall efficiency of healthcare systems [16,17]. These competencies enable healthcare professionals to manage patient data effectively, navigate electronic health records [18,19], process large volumes of information[20], and utilize telemedicine tools [21,22]—capabilities that are no longer optional, but essential and fundamental to healthcare professionals' expertise [10,23,24].

In the present study, digital skills of the Greek study population can be characterized as good, as they are proven to be above the median level, with safety and information skills gathering the highest averages, communication and problem-solving skills being at the median level, and content creation skills being the weakest, with a score just below the median level. It is noteworthy that content creation skills require particular IT knowledge and technical skills, such as developing or maintaining computer systems, hardware, or software, and writing a computer program using a specialized programming language. Thus, they appear as the digital skills category with the lowest proficiency rates in the majority of occupations in Europe [25].

The above levels of digital skills are in line with a similar Greek study, where the digital competence of healthcare professionals is moderate to good [26]. Research conducted on healthcare professionals in European countries shows that the majority have medium levels of digital competence. A study carried out in Moldova found advanced levels of digital skills in the areas of information and communication and moderate levels in the areas of content creation, safety, and problem solving[6]. In Finland, the levels of digital competence are relatively high[27], while in some regions in Finland and Sweden, digital skills are reported as adequate but with several shortcomings[16] and in Catalonia, they appear at a basic and intermediate level [28]. According to the European Centre for the Development of Vocational Training (Cedefop), in terms of digital intensity measurements in the EU for 2021, the level of digital skills for health professionals appears as basic to intermediate, and only in a percentage of 13.4% as advanced [29].

Figure 1: Clustered Bar Mean (95% CI) of Information skills, Mean of Communication skills, Mean of Content creation software skills, Mean of Problem-solving skills, Mean of Safety skills by Hospital (Error Bars: 95% CI).



Consistent with prior research, this study also revealed that younger healthcare professionals demonstrated higher levels of digital competence, particularly in domains such as communication and content creation. Literature suggests that younger professionals tend to exhibit greater eHealth literacy and are more adept at using digital tools [30,31]. This generational disparity in digital skills underscores the need for targeted interventions that provide older healthcare professionals with the necessary training and support to enhance their digital proficiency. Hospital management can organize continuing education programs that are easily accessible and tailored explicitly to older professionals, such as online courses, interactive sessions, or specially designed workplace courses.

It is worth noting that, in the measurement tool, all possible demographic confounding factors were included to avoid biased conclusions. According to the literature review, the demographic factors found to be associated with digital skills levels were age, type of occupation, gender, professional experience, and educational level, which were studied in our research [30,32,33]. However, the results of this study found no significant differences in digital skills based on gender, professional experience, specialty, or educational level.

In addition, research underscores the critical role of the working environment in shaping digital literacy. For instance, De Veer and Francke (2010) observed that attitudes toward electronic health records varied significantly depending on the type of healthcare organization [11]. Similarly, Jarva et al. (2023) as well as Rippen et al. (2013), emphasized that strong organizational support—through timely interventions and the provision of adequate resources—is essential for the successful adoption of digital technologies by healthcare professionals [9,34]. Similarly, the findings of the present survey revealed significant differences in digital skills between military and civilian hospitals, with the predominance of health professionals in military hospitals.

This superiority can be attributed to several factors, including the structured nature of military institutions, where digital training and protocols are more systematically integrated into daily operations [35,36]. Military hospitals often place a stronger emphasis on technical proficiency and operational readiness [37,38], which likely fosters the development of higher digital literacy among their staff. Moreover, they prioritize digital training for their personnel as part of their operational strategies and compliance with applicable protocols. In contrast, civilian hospitals may face a broader array of challenges, including inconsistent administrative policies and slower technology adoption due to resource constraints [35,39].

In Greece, in recent years, the Ministry of Digital Governance, in coordination with the Ministry of Health and other bodies, has been working to strengthen the digital competence of doctors and nurses through the implementation of a national e-health strategy. Among the objectives are to improve the continuous education of health professionals and to ensure access to reliable digital information and tools [40]. However, training programs for civilian health professionals are usually their personal responsibility, as organizational procedures are inadequate. In contrast, in military environments, such programs are supported by the respective military education sectors, financed with their own resources and means, and organized on a regular and periodic basis for the training of all their personnel.

The operation of military hospitals, with adherence to hierarchical procedures, is a significant factor in their ability to implement and train staff in digital technologies efficiently. These institutions often adopt new systems at a faster pace, which may explain the consistently higher levels of digital proficiency observed among healthcare personnel in military settings. Such an organizational advantage aligns with the findings of Ludwick and Doucette (2009), who emphasized that organizational readiness and robust support systems are critical to the successful implementation of electronic health records [41].

Furthermore, the constant exposure to technology [36,42] and digital tools [43,44] observed in military settings provides healthcare professionals with more opportunities to enhance their digital skills. In contrast, civilian hospitals face a variety of challenges that may hinder the development of such competencies. In Greece, these challenges include diverse administrative structures, slower decision-making processes, and limited access to resources for digital training [45,46]. The inherent flexibility within civilian hospital operations may further contribute to inconsistencies in the application and development of digital skills among healthcare professionals. This discrepancy could reflect differences in organizational priorities and the availability of technological resources within these institutions.

A noteworthy area where military healthcare professionals excel is in safety skills, likely due to the stringent data protection and cybersecurity protocols mandated within military environments [47,48]. This focus on safeguarding sensitive patient and operational data, cultivates a more advanced understanding of cybersecurity measures among military hospital staff. Although civilian hospitals also prioritize data security, they often encounter greater challenges in implementing uniform protocols due to variations in organizational structure and resource constraints.

Another significant disparity lies in problem-solving skills. Military healthcare professionals appear to be better equipped to handle technical challenges, potentially due to the emphasis on problem-solving as an integral part of military training and operational effectiveness [49]. In contrast, the less regimented procedures commonly found in civilian hospital settings may provide healthcare professionals with fewer structured opportunities to develop and refine these skills.

We consider that the Ministry of Health or the EU frameworks could adopt military-style training modules emphasizing techniques such as extensive practical training, simulation exercises, the development of specialized centers of expertise, field training techniques, the use of existing training frameworks, needs- and context-based design, continuous harmonization with modern standards, and synergies between civilian and military professionals. One such model is the Common Security and Defence Policy (CSDP) Training Programme, an EU policy to provide senior civil and military officers with the necessary skills and knowledge in crisis management situations [50].

Future Implications

We believe that civil-military cooperation, by embracing strengths and avoiding weaknesses, could improve the overall digital capability of health professionals. As military hospitals provide a more conducive environment for developing digital skills, civilian hospitals could benefit from adopting some of the structured approaches used in military hospitals. With the continuous evolution of healthcare technology, it is essential that all healthcare professionals, irrespective of their work environment, are supported in acquiring and maintaining high levels of digital competence.

Digital skills among healthcare professionals represent a burgeoning field of research that has experienced rapid growth over the past decade. The findings of this study highlight the need to explore further the role of institutional support in fostering digital skills, as well as the factors contributing to digital competence gaps among healthcare professionals across different organizational settings. These results hold international relevance, given the global significance of digital transformation in the healthcare sector. With additional research conducted in similar settings across various countries, these findings could be generalized to further advance digital literacy and transformation in healthcare systems worldwide.

Limitations

This study is subject to three key limitations that may affect the generalizability of the findings. First, the participating nurses were all registered nurses (European Qualifications Framework - EQF 6) and not practicing nurses (EQF 5), and therefore, the measurement tool is validated and reliable only for registered nurses. Second, a self-assessment questionnaire was used as a measurement tool, which entails the risk of subjectivity due to overestimation or underestimation of the actual skills of the participants. Finally, the convenience sampling approach carries the risk of bias and systematic errors.

CONCLUSION

This study underscores the critical importance of digital skills among healthcare professionals, drawing attention to notable differences between staff in military and civilian hospitals. The findings indicate that military healthcare professionals generally demonstrate higher levels of digital competence, likely attributable to the structured and resource-rich environments characteristic of military hospitals. These organizational factors, which foster a more digitally skilled workforce, serve as a foundation for identifying and implementing necessary organizational improvements that healthcare managers can leverage.

However, it is important to note that both military and civilian healthcare professionals exhibited moderate levels of digital skills overall, signifying substantial room for improvement across both settings. Strengthening digital competence across the healthcare sector remains essential for meeting the demands of modern healthcare systems.

CLINICAL PRACTICE

Death due to a rare posttraumatic complication: fat embolism

Cristina Podilă[1], Mihaela C. Șomlea[2], Bogdan A. Buhaș[3], Adrian S. Judea[4], Andreea A. Hleșcu[5], Nicolae Nicoară[4], Flavia Săndoiu[1], Paula Marian[6], Bianca Hanganu[5], Irina S. Manoilescu[5,7]

Abstract: *Fat embolism is a rare complication of high or medium intensity trauma. It is caused by the formation of fat particles in the territories of small terminal circulation, especially at pulmonary, tegumentary and cerebral levels. The mechanism underlying the fat embolism is described by several different theories in literature. In legal medicine, fat embolism raises many controversies upon the diagnostic certainty of the thanatogenerator mechanism leading to death. The occurrence of fat embolism syndrome followed by death must be properly explained so that the fatality can be adequately framed from a legal point of view. In this paper the authors present three cases in which victims of trauma died due to clinically undiagnosed fat embolism, the diagnosis being established only by postmortem histopathological examination. The authors underline the fact that the diagnosis of fat embolism syndrome, although it is a clinical one, it is often established only during autopsy.*

Keywords: *fat embolism, trauma, death, autopsy, diagnosis*

INTRODUCTION

Embolism represents the motion through circulatory blood flow of a material which is not present in blood in normal conditions and its subsequent lodging inside the blood vessels. In the case of fat embolism, the material carried through the blood is represented by fat particles that reach the level of microcirculation. Fat embolism syndrome represents the systemic manifestation of the fat particles being present inside the microcirculation.

Fat embolism was first described by Zenker in 1862 in the case of a railroad worker who died of crushing injuries. In 1873 Bergmann diagnosed fat embolism in a living patient who had suffered a fracture of the femoral bone [1, 2].

The causes of fat emboli formation are multiple, both traumatic and non-traumatic. The most frequent traumatic causes are: long bone fractures, orthopedic procedures, soft tissue trauma (fat tissue laceration), liposuction and mastectomy, neurosurgical interventions. Non-traumatic causes include: acute pancreatitis, extensive burns, diabetes, fatty liver due to diets rich in extrinsic fats and oils [2, 3]. Exceptionally, fat embolism has been observed in cases of hepatic steatosis (in alcoholics and diabetic patients with hepatic damage) due to the destruction of hepatocytes and subsequent release of fat particles [4, 5].

Fat embolism occurs in 90% of patients who have suffered a trauma, but only 2-5% of them develop the fat embolism syndrome; particularly at risk are those with fractures of the long bones. It is difficult to estimate the duration of this syndrome because the symptoms are often subacute or masked by other symptoms of trauma [2, 3].

Post-mortem studies have shown a different but a very high incidence of fat embolism. Thus, a study by Behn C. et al. on 527 autopsies demonstrated the presence of fat embolism in 92 of these [6]. Another study conducted by Hiss et al. in 1996, on 53 victims of aggression followed by death, showed a high incidence of fat embolism. All the subjects studied were young, male, victims of aggressions, suffering severe trauma 24 hours before death. In thirty two cases the presence of fat embolism was observed in the main organs, with no other obvious cause of death. The authors of the study hypothesized that the source of fat embolism was the mechanical disintegration of the subcutaneous adipose tissue [7].

In cases of fat embolism there is a poor correlation between post-mortem and clinical findings. This discrepancy ultimately gave rise to the concept of "iceberg effect of fat embolism" [8- 12]. This justifies, as well as cases with a insufficiently outlined clinical picture for a particular pathology, or a clinical picture that cannot explain the occurrence of death, the importance of forensic autopsy and postmortem laboratory investigations (histopathological and toxicological) in order to establish the thanatogenerator mechanism and the causal link between trauma / illness and death, and ultimately the legal nature of the case, i.e. suicide, accident or homicide [13- 19].

MATERIALS AND METHODS

We present three cases of trauma in which the cause of death was the fat embolism syndrome. All the cases are characterized by a rapid clinical deterioration leading to death, so that a clinical diagnosis of fat embolism syndrome could not be established antemortem.

Case no. 1

Male, 72 years old, chronic alcohol consumer, with past medical history of left femoral fracture and right sided craniotomy, is admitted to hospital for head trauma. At the time of admission physical examination revealed multiple ecchymoses, pain at the pelvic level, lower limbs and abdomen. Clinical and paraclinical investigations established the following diagnosis: minor craniocerebral trauma, facial trauma, posttraumatic subarachnoid hemorrhage, dura mater hygroma, abdominal contusion, pelvic contusion. Surgical intervention was performed to evacuate the dura mater hygroma 6 days after the admission. Evolution was initially favorable. On the 4th postoperative day, the patient developed a febrile syndrome. Laboratory analysis highlighted: elevated leucocyte count (13.390 of which 11.270 neutrofils); elevated serum amylase (225 U/L); lowered erythrocyte count (3.83 milion); hematocrit levels as low as 40.08 %; low thrombocytes count (137.700); increased level of the liver enzyme AST to 48 U/L; low creatinine serum levels (0.69 mg/dl) and reduced glomerular filtration rate to 85 mil/min/1.73 m2. The next day the patient suffered cardiorespiratory arrest that did not respond to resuscitation maneuvers, followed by death. The forensic autopsy was performed. The external examination of the body showed: multiple injuries denoting violence such as ecchymoses and abrasions; signs of medical treatment at the level of the skull, i.e. recent surgical incision and an old whitish scar. The internal examination showed: on the head, 2 craniotomy areas, one of them being recent, subarachnoid hemorrhage, areas of flaccid cerebral structure, small petechial hemorrhagic areas disseminated throughout the brain. The examination of the lungs showed: pulmonary stasis and edema, and areas of pulmonary condensation. Fragments of brain and lungs were harvested during autopsy and subsequently examined by optic microscopy using the Sudan III staining. The microscopic examination revealed fat emboli in the brain and lungs. Following the postmortem macroscopic and microscopic examination we established that the cause of death was the fat embolism syndrome.

Case no. 2

Male, 54 years old, was admitted to the hospital with the diagnosis of: head trauma (subarachnoid hemorrhage, fracture of the left temporal bone with extension to the mastoid bone), face trauma (fracture of right jaw, comminuted fracture of the nose) and chest trauma (left pneumothorax, multiple rib fractures).

The patient was hospitalized for 35 days, during which multiple pleurotomies and bronchoscopies were performed. Laboratory examinations showed: increased leucocyte count (25.170 of which 21.100 neutrofils); low red blood cell count (2.612 milions); low hematocrit (21.240 %); low hemoglobin level (7.793 g/dl); normal thrombocyte count; increased level of AST (103 U/L); increased serum creatinine (4.28 mg/dl); increased GGT levels (93 U/L) and reduced glomerular filtration rate (10.8 mil/min/1.73 m2). Clinical evolution was initially favorable. On day 34 after admission the patient developed a feverish syndrome. The next day he suddenly suffered cardiorespiratory arrest, followed by death. A forensic autopsy was performed. The external examination of the cadaver revealed bruises and signs of recent medical treatment. The internal examination showed: linear head fracture, subdural hematoma under partial resorption, small petechial hemorrhagic areas in the brain, pulmonary edema, and areas of pulmonary condensation. Fragments of organs were harvested (brain, lung) and examined by optic microscopy using Sudan III staining. Following the macroscopic and microscopic examinations we concluded that the cause of death was the fat embolism syndrome.

Case no. 3

Male, 20 years old, victim of a traffic accident, was admitted to the hospital with the diagnosis of: polytrauma due to road traffic accident, major craniocerebral trauma with diffused cerebral edema, multiple rib fractures, fracture of the left iliac wing and left ischial bones, fracture of the left femoral neck, and type III A fracture of the femoral diafisis. Patient was admitted in the hospital for 7 days and underwent a surgical intervention for the femoral fracture. During the first days after the surgery the patient was hemodynamically stable. On day 4 the patient showed tachypnea, tachycardia, and fever and his clinical condition suddenly worsen. The laboratory examinations showed: low leucocyte count (1.56 of which 1.37 neutrofils); reduced numbers of erythrocytes (2.31 milions); low hematocrit (23.3%); low hemoglobin (6.77 g/dl); reduced number of thrombocytes (58.600/ mmc); increase in liver enzyme AST (272 U/L) and ALT (250 U/L); increased serum creatinine (2.43 mg/dl); increased serum urea (94.16 mg/dl) and reduction of glomerular filtration rate to 27.21 mil/min/1.73 m2. Death occurred on the same day. At autopsy, the external examination of the corpse revealed: multiple ecchymoses, abrasions, hematomas, signs of medical treatment. The internal examination showed: brain contusion; multiple rib fractures; pulmonary edema, pulmonary condensation areas, pulmonary infarction; fractures of the pelvis and of the left femor. The microscopic examination of the fragments of brain and lungs collected during the autopsy and stained with Sudan III showed fat embolism. Therefore, based on macroscopic autopsy findings and histo-pathological examination of the brain and lung fragments, we established that the cause of death was the fat embolism syndrome.

RESULTS

In all the three cases the victims suffered various trauma: in the first case the victim suffered soft tissues and head injuries, in the second case the victim suffered a polytrauma with multiple fractures and soft tissue injuries and in the third case the victim suffered craniocerebral trauma, soft tissue injuries and long bone fractures. Therefore, in all the cases, the etiological conditions for the fat embolism occurrence were met. However, in none of the cases the diagnosis was clinically established antemortem. The examination by optic microscopy of the fragments of brain and lungs collected during autopsy and stained with Sudan III showed in all the cases the fat microemboli in the form of orange globes disseminated throughout the fields examined microscopically (figures 1-4) and allowed the postmortem diagnosis of fat embolism. Therefore, in all three cases presented, the results of the histopathological examination of the fragments harvested from the brain and the lungs during the autopsy were essential for determining the cause of death.

DISCUSSION

Fat embolism occurs due to the mobilization of fat cells or fat released by them, followed by their direct penetration into open blood vessels or lymphatic channels. Most emboli have a diameter of 15 to 40 µ; the fat emboli in the lungs are generally larger than those in the large arteries of the systemic circulation [11].

Several theories are mentioned in the literature to explain the pathogenesis of the fat embolism [20].

The mechanical theory shows that mobilization of fat particles occurs due to trauma to the bones or soft tissues. As a consequence, the fat particles released by the trauma enter the venous circulation from where they reach the lungs, where the majority remains, but some of them can also pass into the systemic circulation, reaching other organs.

The biochemical theory, also known as the emulsion instability theory, is mostly useful in explaining the non traumatic fat embolism.

The intravascular coagulation theory holds that in stressing conditions, substances that activate disseminated intra-vascular coagulation and aggregation of fat particles are released.

The toxic trauma theory claims that small blood vessels are affected by high concentrations of fatty acids in the plasma leading to increased vascular permeability.

The mechanical theory is based on the concept of the mobilization of fatty bone marrow from the long bones diaphysis. In the cases presented by us, only one patient suffered a recent fracture of the femur. In the other two cases we have to consider the trauma of soft tissues (hypodermic tissue) as the cause of the fat embolism, by noting that in both cases multiple ecchymoses were observed on the skin.

From a clinical point of view, Gurd and Wilson have developed the major and minor criteria which allow which allow for the diagnosis of fat embolism. The major criteria are: axillary or subconjunctival petechiae; hypoxaemia ($PaO2 <60$ mm Hg, $FIO2 = 0$); central nervous system depression disproportionate to hypoxaemia; pulmonary oedema; radiological signs and symptoms of respiratory insufficiency; cerebral changes unrelated to a cranial trauma or other illness; rash. The minor criteria are: tachycardia more than 110 bpm; pyrexia more than 38.5°C; fat globules present in urine; changes in renal function (reduced urine output); drop in haemoglobin level (more than 20% of the value upon admission); drop in haematocrit values; drop in platelet values (more than 50% of the value upon admission); increased erythrocyte sedimentation rate (greater than 71 mm per hour); fat globules present in the sputum; emboli present in the retina; tachicardia; fever; renal insufficiency; sudden thrombocytopenia. According to Gurd and Wilson the diagnosis of fat embolism can be established if either one major criterion and 4 minor criteria or 2 major criteria are met [21].

Lindeque suggested that the criteria of Gurd and Wilson may under-diagnose the syndrome, and proposed the following criteria based on respiratory parameters: Pao2 kPa of less than 8Fio2 0.21; Paco2 kPa or pH of less than 7.3 or more than 7.3; respiratory rate greater than 35 breaths/min−1 even after adequate sedation; increased breathing efforts showed by: dyspnea, use of accessory muscles, tachycardia and anxiety [22]. Any patient with a fractured femur and/or tibia, presenting one or more of these criteria, was diagnosed with fat embolism syndrome. These criteria led to the diagnosis of fat embolism syndrome in 29% of patients in a series of 55, which is higher than other series, especially since this study excludes patients with thoracic lesions, where some of Lindeque's clinical signs may appear in the absence of fat embolism [22].

Petechial eruption is considered a pathognomonic clinical sign for fat embolism syndrome. It may occur in about 60% of patients, usually on the conjunctiva, on the oral mucous membrane and on the skin of the neck and shoulders. This distribution can be explained by the drops of fat that accumulate in the aortic arch before the independent embolization at skin level through the subclavian and carotid vessels [20, 23-25]. The factors contributing to the petechial eruption are: stagnation of blood, loss of coagulation factors and platelets, and damage to the endothelial walls due to free fatty acids (FFA) leading to rupture of capillaries [25].

In the vast majority of cases, the fat embolism remains asymptomatic, and the fat emboli are dispersed into small cells and phagocyted by macrophages or embedded in hepatic cells [26, 27]. Thus, many cases remain undiagnosed before death.

In the three cases presented, the symptomatology before death was poor and unspecific (febrile syndrome, tachycardia, tachypnea), and remained undiagnosed. The diagnosis of fat embolism syndrome was established only after performing the autopsy, and the histopathological examination of the brain and lung fragments stained specifically with Sudan III. Therefore, for post mortem diagnosis of fat embolism syndrome, it is essential to perform a histopathological examination with special stains that highlight the presence of fat emboli in the tissues and organs.

In the cases presented in this paper, fat embolism at the pulmonary and cerebral level was observed. According to literature, brain and lung localizations are the most important, although in most cases pulmonary fat embolism remains clinically asymptomatic. In order to be able to certify fat embolism as the cause of death, it is necessary for histopathological examinations to find fat emboli on a large part of the examination fields. The gravity of the consequences of pulmonary embolism also depends on the size and amount of fat emboli, as well as whether or not they pass into the systemic circulation to the lung.

In the brain, emboli produce small petechial hemorrhages, areas of ischemic necrosis and hemorrhage or necrosis and demyelination. Cerebral embolism is considered in literature as a paradoxical event, because it requires the presence of cardiac atrial septal defects in order to be explained. In the presented cases, there was no autopsy finding that showed neither atrial or ventricular septal defects nor patent arterial canal that could explain the cerebral fat embolism. An explanation of the pathophysiological mechanism which determined the cerebral embolism could not be found in this study.

The cause of death in all the three cases presented in this paper was the fat embolism. The diagnosis was established with certainty only after autopsy, by a histopathological examination which revealed the presence of fat emboli in the lung and brain tissues. Of the cases presented only one suffered a recent fracture of the femur; another presented in addition to trauma paraclinical changes suggestive of acute pancreatitis as a contributing factor; none had cardiac malformations that could explain the paradoxical fat embolism in the brain; all of the cases showed multiple lesions of the subcutaneous tissue and death occurred shortly after the initial trauma or after surgical interventions.

Death due to fat embolism can fall into the category of violent or non-violent deaths. Regardless of the cause of fat embolism, from forensic point of view the fat embolism is considered a complication that leads to a secondary causal relationship; in other words between the trauma/ initial pathology and death an intermediate link is inserted represented by a complication (the fat embolism) which is connected to a greater or lesser extent to the initial trauma/ pathology [28-30].

CONCLUSION

From forensic point of view, the diagnostic certainty in posttraumatic lesions is a priority objective. From the diagnosis it is possible to reconstruct the thanatogenerator mechanism and finally it can be useful to respond to the legal aspects of the case, i.e. the causal relationship between trauma and death.

In the case of trauma with reduced thanatogenerator potential, which usually evolve without complications, the occurrence of fat embolism syndrome followed by death must be appropriately explained so that the case can be properly framed from a legal point of view. It is important to emphasize that the histopathological examination using specific stainings, such as Sudan III, has a fundamental and incontestable role in the diagnosis of fat embolism and in estimating its gravity, and therefore, its implication in the occurence of death.

Abstract: Malignant melanoma and urological cancers originate from different tissues and organs, yet several studies highlight connections between these malignancies, including common risk factors, genetic predispositions, and immunological pathways. Evidence from recent studies suggests that a prior diagnosis of melanoma may increase the likelihood of subsequently developing renal cell carcinoma (RCC), and, conversely, patients with RCC appear to face a heightened risk of being diagnosed with melanoma. Shared factors such as a personal or family history of cancer, UV radiation exposure, smoking, and obesity have all been linked to an increased incidence of various cancer types. A major link between malignant melanoma and urological cancers is the presence of shared genetic mutations and familial cancer syndromes. Key mutations, including germline mutations in BRCA1, MITF, CDKN2A, TP53, and alterations in the PI3K/AKT pathway, significantly contribute to the risk of both types of malignancies. Personalized medicine, which tailors prevention and treatment strategies to an individual’s genetic, environmental, and lifestyle factors, has significantly improved cancer care. The primary aim is to select the most effective treatment for each patient, maximizing therapeutic outcomes, reducing side effects, and minimizing the risk of drug resistance. Advances in genomics and immunology are driving the development of personalized therapies that target specific molecular pathways and immune responses common to both melanoma and urological cancers. Angiogenesis inhibitors and checkpoint inhibitors have demonstrated notable success in treating these cancers, with tumor mutational burden serving as a valuable biomarker for predicting the efficacy of immune checkpoint inhibitors.

Keywords: malignant melanoma; urological cancers; risk factors; shared genetic mutations; lifestyle changes; personalized treatment; tumor mutational burden; angiogenesis inhibitors; checkpoint inhibitors

INTRODUCTION

Cancer currently ranks as the leading cause of mortality worldwide. The growing number of cases and related deaths is primarily driven by shifts in demographic patterns, such as population aging and growth, along with greater exposure to environmental and lifestyle-related carcinogenic factors [1].

Although malignant melanoma and urological cancers arise from different anatomical sites and tissues, multiple studies have identified links between them. These connections include overlapping risk factors, common genetic susceptibilities, and similarities in immune-related pathways involved in their development.

Gaining insight into the association between malignant melanoma and urological malignancies may contribute to the improvement of approaches for early diagnosis, risk reduction, and therapeutic management.

Although melanoma accounts for less than 2% of cancer cases globally, it remains one of the most frequently diagnosed malignancies across Europe (5th place). Survival outcomes have improved considerably in recent years, with the overall 5-year survival now approaching 93.3%. However, patients diagnosed with stage IV disease continue to face a poor prognosis, as the survival rate in advanced stages drops significantly, reaching only 29.8% [2].

Urological cancers (UC), which include kidney, bladder, prostate, testicular, penile, and urethral cancers, differ significantly in incidence, risk factors, and prognosis.

Renal cell carcinoma (RCC) represents roughly 3% of all malignant tumors diagnosed globally. The occurrence of this malignancy tends to be more frequent in industrialized nations, especially in Western societies, where lifestyle habits, environmental risk factors, and advancements in medical imaging likely play a role in higher diagnosis rates. Renal cell carcinoma represents a major public health issue due to its frequently silent evolution in early stages and the elevated risk of distant spread if not recognized in time [3]. Globally, it is estimated that more than 430,000 new cases are identified annually, underlining the increasing impact of this disease on healthcare systems. Of these cases, approximately 138,000 are reported in Europe alone, underscoring the significant prevalence of RCC across the continent. Such statistics emphasize the importance of ongoing efforts in early detection, prevention, and the development of effective treatment strategies. [4].

Urothelial carcinoma is the second most common urological malignancy in developed countries [5]. Bladder cancer (BC) accounts for 90–95% of the UC [6]. It ranks as the seventh most frequently diagnosed cancer among men globally [7].

Primary urethral carcinoma is considered a rare cancer, accounting for < 1% of all genitourinary malignancies [8].

Approximately 1.5 million new cases are reported worldwide each year. This high incidence places it as the second most commonly identified malignancy in the male population [9].

Testicular cancer (TC) accounts for 1% of adult neoplasms and 5% of urological tumors. Its incidence has risen in recent decades, particularly in industrialized countries, and continues to increase [10].

Penile cancer is a rare condition in industrialized countries, with an incidence of approximately 1 per 100,000 men in Europe and 0.5 per 100,000 in the USA [11].

The aim of this article is to evaluate the potential connections between malignant melanoma and the most common urological cancers—renal cancer, bladder cancer, and prostate cancer—from the perspectives of epidemiological factors, shared genetic mutations and molecular pathways, clinical implications, and personalized medicine.

EPIDEMIOLOGICAL LINKS

Environmental and Lifestyle Risk Factors for Malignant Melanoma and Urological Cancers

Advancing age, genetic predisposition, prior cancer diagnoses, radiation exposure (such as ultraviolet rays), contact with certain hazardous substances, tobacco use, alcohol intake, and excess body weight are all factors that have been linked to a higher likelihood of developing different forms of cancer.

Ultraviolet (UV) exposure and vitamin D

The role of ultraviolet (UV) sunlight radiation in the development of skin cancers, particularly malignant melanoma, is well-established. UVA (320–400 nm) penetrates deeper into the skin, leading to indirect DNA damage through reactive oxygen species (ROS), while UVB (280– 320 nm) directly damages DNA by inducing cyclobutane pyrimidine dimers [12]. UVB radiation can also induces mutations in genes such as TP53 and BRAF, contributing to melanomagenesis [13].

However, the association between UV exposure and RCC remains unclear, recent studies have attempted to clarify the relationship but have produced mixed results. Grasso et al. [14] found no statistically significant differences between sun exposure in patients affected by kidney cancer and controls, both during childhood and adult life. Contrary to this, Karami et al. [15] suggest that among males there is an inverse association between occupational UV exposure and renal cancer risk. Replication studies are warranted to confirm these results.

Similar to the RCC, the potential involvement of vitamin D in the development and progression of bladder cancer and upper urinary tract urothelial tumors remains underexplored. Recent epidemiological studies offer conflicting results regarding the potential link between blood levels of vitamin D and the risk of bladder cancer onset. However, several investigations suggest that individuals with a higher intake of vitamin D through diet, particularly when not accompanied by elevated calcium consumption, may have a reduced risk of developing bladder malignancies [16]. In a meta-analysis, Zhang et al. [17] concluded that Vitamin D deficiency has been linked to a heightened risk of bladder cancer. According to Gislefoss et al. [18] educed serum concentrations of 25-hydroxy vitamin D, along with obesity, may be linked to a higher risk of developing bladder cancer. The 2024 guidelines of the European Association of Urology (EAU) highlight that both insufficient and excessive levels of vitamin D have been linked to a higher likelihood of developing prostate cancer, with a particularly stronger connection observed in cases involving high-grade tumors [19,20]. Additionally, Murphy et al. demonstrated that Vitamin D deficiency was linked to higher Gleason scores and advanced tumor stages at diagnosis [21].

Smoking

The effect of smoking on melanoma outcome still remains an enigma [22]. In a recent study, Arafa et al. [23] found that individuals who currently smoke or have a heavy smoking history tend to exhibit a greater susceptibility to developing squamous cell carcinoma (SCC), while simultaneously displaying a lower probability of malignant melanoma. Interestingly, no significant relationship was observed between past smoking and the overall risk of skin cancer. In contrast to established risk patterns, a case-control study by Sondermeijer et al. [24] reported an inverse association between cigarette smoking and melanoma incidence in men. However, smoking remains a well-documented risk factor for various urologic malignancies.

Smokers face a significantly elevated likelihood—estimated at around 1.5 times higher—of being diagnosed with renal cell carcinoma (RCC) when compared to non-smokers [25]. Encouragingly, long-term smoking cessation has been shown to gradually diminish this elevated risk [26]. Multiple carcinogens (N-nitrosodimethylamine (NDMA) and N-nitrosodiethylamine (NDEA), polycyclic aromatic hydrocarbons (PAHs), Cadmium and lead (Pb), 2-naphthylamine) are absorbed through the lungs into the bloodstream and then lipophilic carcinogens may accumulate in renal tissue [27].

Cigarette smoking represents the leading modifiable contributor to bladder cancer development and is estimated to be responsible for nearly half of all diagnosed cases [28]. Low-tar cigarettes are not associated with a lower risk of developing BC. The risk associated with electronic cigarettes has not been adequately assessed. Research by Bjurlin et al. [29] revealed the presence of carcinogen-related biomarkers in the urine of individuals who use e-cigarettes, several of which have a well-established association with bladder cancer. Kispert et al. [30] recently presented a study showing that smoking is associated with increased accumulation of platelet-activating factor (PAF) and elevated expression of the PAF receptor (PAF-R), which may contribute to tumor progression and metastasis in smokers.

Current cigarette smoking has been linked to an increased risk of prostate cancer (PCa) mortality, as well as more aggressive tumor characteristics and a poorer prognosis, even after smoking cessation [31].

Obesity

Obesity promotes chronic inflammation, a recognized risk factor for cancer development. Inflammatory cytokines can stimulate the growth of both melanoma and renal cell carcinoma (RCC), potentially linking these two malignancies in obese patients [32].

Obesity appears to be associated with malignant melanoma, particularly in patients with a BMI >30 [2].

Several retrospective studies have shown that obesity appears to be a factor that positively influences the prognosis of patients with RCC, called the "obesity paradox" [33]. Recently, Graff and colleagues [34] provided a comprehensive review with the main purpose of disentangling the "obesity paradox" in renal cancer. The results support obesity with a BMI >35 as a risk factor for total and fatal RCC. They undermine the obesity paradox by suggesting that weight loss around diagnosis, and not low BMI itself, is associated with worse prognosis.

In the REDUCE study [35], obesity was associated with a lower risk of low-grade PCa and a higher risk of high-grade PCa.

Occupational Exposure

Occupational exposure to carcinogens can increase the risk of various cancers. One common risk factor for both malignant melanoma and urological cancers is exposure to polycyclic aromatic hydrocarbons.

In a 45-year follow-up study conducted across five Nordic countries, Pukkala et al. [36] found an elevated incidence of prostate cancer, malignant melanoma, non-melanoma skin cancer, and lung adenocarcinoma among firefighters, with skin absorption identified as a primary route of exposure. Similarly, individuals working in the petroleum industry are exposed to comparable risks [37].

According to the 2024 EAU Guidelines [38], occupational exposure to polycyclic aromatic hydrocarbons and other aromatic amines or hydrocarbons, mainly in the paint, dye, or petroleum industries, is the second most important risk factor for bladder cancer.

While certain studies have indicated a potential association between occupational exposure to polycyclic aromatic hydrocarbons and an increased risk of renal cancer [39,40], there is no high-quality evidence to definitively confirm this link [41].

SHARED GENETIC MUTATIONS AND MOLECULAR PATHWAYS

Integrating molecular profiling into clinical oncology practice, particularly through mutation-focused approaches, has become essential in the evolution of precision medicine. By identifying specific genetic alterations within tumors, clinicians can better tailor immunotherapeutic interventions that modulate immune checkpoints. Therapeutic approaches that focus on modulating immune checkpoints have identified key molecular pathways, such as those involving PD-1 and its ligand, as well as CTLA-4, as critical elements in regulating immune responses against tumors. Targeting these mechanisms has opened promising prospects for the treatment of a wide range of cancers [42]. These immunotherapeutic agents have significantly reshaped treatment approaches across several types of cancers with overlapping characteristics.. Such technology was entirely unavailable before the completion of the Human Genome Project in 2001 [43]. However, current advances now enable the routine identification of relevant therapeutic mutations in many cancers, particularly in malignant melanoma and also in UC.

Genetic Mutations in Malignant Melanoma

Melanoma exhibits one of the highest mutation frequencies among cancers [44]. The most frequent mutations are BRAF, NRAS, NF1, the TERT promoter, and CDKN2A, while KIT and TP53 mutations occur at a much lower frequency. [45].

- The BRAF mutation is the most common in malignant melanoma, occurring in 2/3 of these patients. [46]. This BRAF mutation (especially the BRAF V600 mutation) promotes cellular growth and inhibits apoptosis and is more commonly found in patients with intermittent sun exposure compared to those with chronically sun-exposed skin or unexposed skin [47].

- NRAS mutations. Among the three main proto-oncogenes of the RAS family (NRAS, KRAS, and HRAS), NRAS mutations play a key role in continuously activating pathways that lead to cell growth, proliferation, and cell cycle dysfunction. They are found in approximately 1/4 of patients with malignant melanoma, particularly in those with non-exposed skin, and are associated with aggressive clinical forms and poor prognosis [48,49].

- The neurofibromatosis type 1 (NF1) mutation leads to a loss of function in certain tumor suppressors. NF1 mutations appear to be correlated with high UV exposure, resulting in a high mutational burden [50,51].

- The TERT (telomerase reverse transcriptase) promoter mutation is a UV-induced mutation associated with poor clinical prognosis. This mutation typically occurs in the promoter region, resulting in increased expression of the gene [52].

- CDKN2A Mutation. The CDKN2A gene contributes to cellular homeostasis by limiting uncontrolled cell division through mechanisms that halt the progression of the cell cycle. Its function is essential in preventing the unchecked proliferation characteristic of tumor development. When mutations occur in this gene, normal growth regulation is disrupted, promoting tumor development. Individuals who carry CDKN2A mutations face a markedly increased risk of developing multiple primary melanomas, often at an earlier age. [53,54].

- KIT is a proto-oncogene receptor tyrosine kinase and binds to stem cell factor. By activating the KIT protein, cell growth, proliferation, survival, and migration can be affected. KIT mutations occur more commonly in areas of chronic sun damage [55].

- BAP1 Tumor Predisposition Syndrome (BAP1-TPDS) is an inherited cancer syndrome marked by germline mutations in the BRCA1-associated protein 1 (BAP1) gene [56]. The consequences include genomic instability, uncontrolled cell proliferation, and resistance to apoptosis. In the case of cutaneous melanoma, patients with germline mutations in BAP1 develop multiple atypical melanocytic lesions (dome-shaped, skin-colored to reddish papules), which are histologically distinct from conventional melanomas [57,58].

- TP53 Mutation. In human biology, the TP53 gene plays a major role in preserving genomic integrity and is often described as the "guardian of the genome." This designation stems from its crucial function in cellular defense mechanisms, particularly in detecting DNA damage and initiating appropriate responses such as cell cycle arrest, DNA repair, or apoptosis. By preventing the propagation of cells with genetic errors, TP53 serves as a key tumor suppressor and a vital component in maintaining cellular homeostasis and protecting against malignant transformation [10]. The TP53 mutation has been found in association with BRAF, NRAS, and NF1 mutations and seems to appear at a later stage in tumor development. Even though TP53 is rarely mutated in melanoma, reduced levels of p53 contribute to aggressiveness and resistance to therapy for patients with malignant melanoma [59,60].

Genetic Mutations in Urological Cancers

There is increasing evidence that genetic susceptibility factors and familial associations may influence the incidence of UC, although their role is not as well defined as in the case of malignant melanoma.

- BAP1 Tumor Predisposition Syndrome (BAP1-TPDS) can predispose individuals not only to cutaneous and uveal melanoma but also to renal cell carcinoma (RCC) [57].

In case of cutaneous melanoma, patients with Germline mutations in BAP1 develop multiple atypical melanocytic lesions (dome-shaped, skin-colored to reddish papules), histologically distinct from conventional melanomas [58].

Kapur et al [61] in a retrospective analysis on 145 patients with primary clear cell renal cell carcinoma (ccRCC) concluded that in RCC, the clear cell subtype (ccRCC) germline mutations occur in approximately 10–15% of ccRCC. This study concluded that these patients are associated with poorer overall survival compared to those without the mutation.

Studies on the expression and prognostic role of BAP1 in prostate cancer are currently lacking. However, Steurer et al. immunohistochemically analyzed more than 17,000 prostate cancer cases, assembled on a tissue microarray over 10 10-year period, and concluded that their study shows BAP1 upregulation is associated with prostate cancer progression and aggressiveness [62].

- CDKN2A Mutation. The role of CDKN2A mutations in renal cell carcinoma is less clear. Recently, in a study, Kiatprungvech and colleagues [63] demonstrated that CDKN2A mutations may be associated with higher tumor grade and poorer prognosis in RCC, development, and sarcomatoid changes.

Deletions of CDKN2A are a molecular risk factor for tumour progression in non-muscle-invasive bladder cancers, an indicator of increased aggressiveness and worse prognosis in muscle-invasive bladder cancers [64].

In a meta-analysis investigating the involvement of CDKN2A methylation in prostate cancer, Cao et al. [65] found no strong evidence supporting a significant association between this epigenetic alteration and the onset or advancement of the disease. Nevertheless, lower levels of CDKN2A expression were correlated with poorer disease-free survival outcomes, suggesting potential prognostic relevance.

- MITF Mutation. The Microphthalmia-associated Transcription Factor (MITF) regulates genes involved in melanogenesis, melanocyte survival and proliferation, and DNA repair. The MITF-E318K variant is a heterozygous missense mutation characterized by the replacement of glutamic acid with lysine at the 318th amino acid position in the protein sequence.. Carriers have a higher risk of developing early-onset melanoma [66].

This mutation was also identified in patients with RCC, suggesting a shared genetic risk factor with melanoma. In their study, Lang et al. [67] observed that the presence of the pathogenic MITF variant in a family with bilateral and multifocal type 1 papillary renal cell carcinoma reinforces its potential role as a genetic risk factor for RCC. These findings also highlight the need to consider MITF variant screening regardless of the tumor's histological subtype.

- TP53 mutation. The role of the p53 pathway in renal cancer is underestimated. In RCC, there is a low rate of p53 mutations, which leads to poor response to conventional therapies or even therapy resistance [68].

According to findings reported by Wu et al. [69], alterations in the TP53 gene were identified in half of the individuals diagnosed with bladder cancer. It is worth noting that these genetic alterations appeared with greater frequency in tumors that had penetrated the bladder's muscular layer, as opposed to those confined to the superficial, non-muscle-invasive stages. Patients with TP53 mutations were associated with lower TP53 mRNA expression levels, more advanced tumor stages, and higher histologic grades.

- Loss of function in the VHL gene, often caused by inherited mutations, is associated with the development of von Hippel-Lindau hereditary cancer syndrome. This rare genetic condition can predispose affected individuals to various tumor types, including, in some cases, clear-cell renal cell carcinoma [70].

- Alterations in the BRCA1 and BRCA2 gene pathways have been linked to more aggressive disease phenotypes and less favorable prognoses in individuals affected by metastatic castration-resistant prostate cancer [71]. Specifically, inherited BRCA2 mutations are frequently observed in early-onset prostate cancer and are recognized as independent predictors of metastatic progression and reduced prostate cancer-specific survival [72,73]. Nyberg and colleagues [74] in a prospective cohort study confirmed the BRCA2 association with aggressive PCa. This mutation does not occur in other urological cancers or malignant melanoma.

CLINICAL IMPLICATIONS AND PERSONALIZED MEDICINE

Prevention is the main principle in reducing morbidity and mortality, as well as in lowering healthcare system costs.

Personalized medicine, which customizes prevention and treatment strategies based on an individual's genetic, environmental, and lifestyle factors, has greatly advanced cancer care [75].

Understanding the link between malignant melanoma and urological cancers is a key advancement toward personalized medicine.

Identifying genetic mutations and syndromes that link melanoma to urological cancers highlights the importance of genomic profiling in cancer diagnosis and treatment. The development of next-generation sequencing (NGS) technologies has made it possible to identify particular genetic alterations that may increase a person's susceptibility to various types of cancer or impact how they respond to specific therapeutic interventions [76].

Tailoring Prevention Strategies (Table 1).

Reduce Ultraviolet Exposure and the Role of Vitamin D

Excessive UV exposure is widely recognized as the leading environmental risk factor for melanoma. In people with an increased hereditary predisposition to skin cancer [77], tailored prevention approaches may involve regularly applying sunscreens that offer protection against both UVA and UVB rays, opting for clothing that minimizes sun exposure, and refraining from the use of artificial tanning devices.

In a systematic review and meta-analysis, Song et al. [78] concluded that a moderate dietary vitamin D supplement to prevent serum 25(OH)D deficiency may be beneficial for the long-term survival of melanoma patients.

A prospective study conducted by Lin et al. [58] suggested that exposure to ultraviolet radiation may be associated with a reduced incidence of prostate cancer. Additionally, research has shown that both low and excessively high levels of vitamin D may contribute to a higher likelihood of developing prostate cancer, particularly in cases involving more aggressive tumor forms [19]. Therefore, maintaining normal vitamin D levels is essential.

Table 1: Recommendations for lifestyle changes

	Malignant melanoma	**RCC**	**Bladder cancer**	**Prostate cancer**
Smoking cessation	uncertain	yes	yes	yes
Reduce ultraviolet exposure	yes	-	-	no/increase
Vitamin D	moderate increase dietary	normal vitamin D levels		
Obesity	uncertain	yes	yes	yes
Dietary antioxidants	yes	yes	yes	yes

Smoking Cessation in Malign Melanoma and Urological Cancers Prevention

While the relationship between smoking and malignant melanoma remains inconclusive, tobacco use is widely recognized as a major contributor to the development of several urologic malignancies, especially bladder cancer and renal cell carcinoma. Smoking cessation programs, aided by pharmacological treatments such as nicotine replacement therapy (NRT), have proven effective in reducing the incidence or recurrence of progression of RCC [26] and bladder cancer [80]. In a network meta-analysis of 20 randomized controlled trials, Gou et al. [81] concluded that Varenicline and Bupropion increased the odds of smoking abstinence.

Obesity and Dietary Interventions in Malignant Melanoma and Urological Cancers Prevention

Studies that focus specifically on the link between obesity and melanoma prognosis are limited [61]. Obesity may be a risk factor for bladder cancer recurrence [83] and a higher risk of death from prostate cancer [84].

The use of dietary antioxidants has shown promising results in studies, supporting the potential role of antioxidants in the prevention of malignant melanoma related to UV exposure.

Obesity and dietary habits are well-established risk factors for prostate cancer and RCC.

Personalized weight management programs guided by genetic and metabolic profiles, and dietary recommendations, such as reducing red and processed meats and increasing intake of plant-based foods rich in antioxidants (e.g., lycopene), regular physical activity, are essential for individuals at high risk for prostate cancer and RCC [64,65].

Screening and Surveillance

Patients with a history of melanoma or urological cancer need careful monitoring for the potential development of additional malignancies. Routine screenings, such as skin examinations and urological assessments, can aid in early detection and improve patient outcomes. Screening for malignant melanoma is recommended for individuals with certain risk factors, including family or personal history, lifestyle or occupational predispositions, and being an older white male.

Patients with germline mutations in BAP1, CDKN2A, MITF, and other cancer-related genes may benefit from more extensive cancer screening protocols. These could include regular skin examinations for melanoma, imaging studies to detect urological cancers, and continuous monitoring for other associated malignancies.

Skin cancer screening remains a topic of debate.

There is an ongoing debate regarding the value of routine screening for skin cancer.

According to current assessments by major public health authorities, existing evidence is insufficient to clearly confirm or reject the benefits of regularly screening asymptomatic adults in the general population [87]. In contrast, screening is recommended for high-risk individuals by both the Australian Cancer Network [88] and the Canadian Cancer Society [89].

The group of patients at higher risk for developing skin cancer includes individuals with a personal history of skin cancer, those with light-colored skin, eyes, and hair, a high number of moles or freckles, and a history of multiple blistering sunburns during childhood [87]. In individuals at elevated risk, initial screening typically involves assessment of skin lesions using the "ABCDE" criteria, focusing on asymmetry, irregular borders, variations in color, and lesions exceeding 6 mm in diameter. Another widely used approach is the visual examination of the skin to detect pigmented lesions that appear noticeably different from the patient's other moles, a method commonly referred to as the "ugly duckling" sign [90].

The American Academy of Dermatology advises that patients diagnosed with cutaneous melanoma undergo cancer risk counseling if they present specific risk factors. These include having a family history involving three or more relatives on the same side affected by invasive melanoma or pancreatic cancer; the presence of three or more primary invasive melanomas, particularly if at least one was diagnosed before the age of 45; the occurrence of one or more melanocytic BAP1-mutated atypical intradermal tumors (MBAITs) accompanied by a family history of cancers such as mesothelioma, meningioma, or uveal melanoma; the presence of two or more MBAITs; or a broader family history that includes other forms of cancer. [91]. According to the National Comprehensive Cancer Network (NCCN), genetic testing for p16/CDKN2A mutations is advised in cases where an individual or family history includes three or more invasive cutaneous melanomas, or a combination of invasive melanoma, pancreatic cancer, and/or astrocytoma. Furthermore, individuals diagnosed with invasive cutaneous melanoma who also have a first-degree relative affected by pancreatic cancer are considered appropriate candidates for genetic evaluation. [92].

Renal cancer screening.

There is currently no evidence to support primary screening in the general population. The most pragmatic approach is to screen high-risk individuals or integrate this screening with other routine screening programs. This strategy improves the cost-effectiveness ratio, particularly for patients at risk of RCC [93]. Genetic assessment is advised in individuals under the age of 47, as well as in those presenting with tumors affecting both kidneys or multiple sites within the same kidney. It is also warranted for patients who have a direct or extended family history of renal cell carcinoma or relatives carrying a confirmed pathogenic genetic alteration. Additionally, testing is appropriate when histopathological characteristics raise suspicion of an inherited subtype of renal cancer [94].

Bladder cancer screening.

Current evaluations by major public health experts indicate a lack of sufficient high-quality evidence to clearly assess whether bladder cancer screening in asymptomatic adults provides more benefits than harms [95]. Similar recommendations are also found in the EAU Guidelines 2024 [96].

Prostate cancer screening.

Screening for PCa is still controversial. [97]. Prostate screening is associated with an increased diagnosis of prostate cancer (PCa), the detection of more localized disease, and fewer cases of advanced PCa. However, no PCa-specific survival benefit has been observed, and there has been no overall survival (OS) benefit [98]. Consequently, population-based screening has not been widely adopted.

According to the 2024 EAU Guidelines, PSA testing for prostate cancer screening is recommended for well-informed men at higher risk of PCa. It is generally recommended for men aged 50 and above. Earlier screening may be appropriate for those over 45 who have close relatives previously diagnosed with the disease or who belong to high-risk populations, such as individuals of African ancestry. Furthermore, men with confirmed BRCA2 mutations are advised to initiate screening starting at age 40 [99].

Hereditary genetic testing is recommended for men who have several relatives affected by prostate cancer at a relatively early age—specifically before turning 60, or in cases where a family member has died as a result of the disease. Genetic testing may also be appropriate for men who have a familial pattern of high-risk inherited mutations or a history of multiple cancer diagnoses occurring on the same side of the family [99].

Personalized Treatment

The goal of personalized medicine for cancer patients is to select the most effective treatment tailored to each individual, aiming for maximum efficacy, reduced side effects, a lower risk of drug resistance, and ultimately, improved overall survival. With advancements in technology, genetic testing has become increasingly accessible and is now part of routine clinical practice. [100]. Advancements in genomics and immunology are driving the development of personalized treatments that focus on specific molecular pathways and immune mechanisms common to both melanoma and urological cancers. The convergence of these genetic pathways offers promising potential for the creation of targeted therapeutic approaches.

In most cancer cases, treatment follows well-established standards that are outlined in specialized guidelines. It includes surgical therapy (nephrectomy, prostatectomy, radical cystectomy, melanoma surgery, etc.), radiotherapy, and/or hormone therapy.

In the final stages, palliative therapies are offered to patients with metastatic cancer, and these treatments can help enhance quality of life while potentially prolonging disease-free survival.

Angiogenesis inhibitors and immunotherapies have shown notable effectiveness in treating malignant melanoma and urological cancers, particularly kidney and bladder cancers. Most prostate cancers exhibit resistance to immunotherapies, particularly immune checkpoint inhibitors [101].

Angiogenesis inhibitors.

VEGF inhibitors function by blocking the interaction between VEGF and its receptors (VEGFRs) on endothelial cells, effectively stopping the signaling processes responsible for initiating new blood vessel formation [102]. VEGF inhibitors are primarily categorized into two groups: monoclonal antibodies, which bind directly to VEGF ligands to prevent receptor interaction, and tyrosine kinase inhibitors (TKIs), which target VEGFRs along with associated kinases to block angiogenesis signaling pathways [103,104]. These inhibitors have shown notable effectiveness in adjuvant treatment for renal cell carcinoma (RCC) and malignant melanoma, though their use is more restricted in other types of urological cancers.

Monoclonal VEGF antibodies, particularly Bevacizumab, have demonstrated effectiveness in the treatment of both renal cell carcinoma (RCC) and malignant melanoma [105,106].

Tyrosine kinase inhibitors are commonly prescribed as initial or subsequent targeted treatments for patients with kidney cancer that has progressed locally or spread to distant sites [107,108]. Initial treatment with sunitinib alone has demonstrated significant benefits by delaying disease progression and enhancing the overall tumor response. Some tyrosine kinase inhibitors, such as pazopanib, have shown similar effectiveness to sunitinib when used in the initial treatment of patients with metastatic kidney cancer [109]. Certain agents, including cabozantinib, have shown clinical benefit in patients with advanced clear-cell renal cell carcinoma that no longer responds to therapies targeting the VEGF receptor pathway. This option is particularly relevant for individuals who have not yet received immune checkpoint inhibitors and who have previously undergone one or two systemic treatment regimens [110].

For patients with malignant melanoma, sunitinib may show efficacy, particularly in those with KIT mutations [111].

Checkpoint inhibitors

Immunotherapeutic strategies—especially those directed at modulating checkpoint pathways—have shown significant efficacy in the treatment of various cancers. A prominent category within these therapies includes drugs designed to block the binding between PD-L1 and its associated receptor, PD-1, both of which are crucial in helping tumors evade immune surveillance. Interrupting this interaction enables the reactivation of T cells, thereby strengthening the immune system's capacity to detect and destroy malignant cells.

Tumor mutational burden (TMB) serves as an essential biomarker for predicting immunotherapy outcomes, representing the total count of somatic mutations within a tumor's DNA. Although tumor mutational burden (TMB) does not appear to impact the success of treatments aimed at inhibiting angiogenesis, it is considered an important biomarker in forecasting patient responsiveness to immunotherapeutic strategies. These treatments work by altering specific immune checkpoints involved in immune regulation, including pathways mediated by proteins like PD-1, PD-L1, and CTLA-4 [112]. Tumors with a high mutational burden typically generate a higher quantity of neoantigens (abnormal proteins created by genetic mutations). This abundance of neoantigens improves the chances of immune system recognition and response, thereby boosting the effectiveness of immunotherapy [113]. Cancers such as melanoma, lung cancer, and urothelial cancers often have a high tumor mutational burden (TMB), while prostate and breast cancers typically show lower TMB [69]. Tumors with high TMB tend to express a wider array of neoantigens, making them more prone to immune system recognition and response, particularly when treated with checkpoint inhibitors. As a result, immunotherapy is generally more effective in cancers with elevated TMB [114,115].

Both malignant melanoma and RCC are highly immunogenic tumors, meaning they can provoke an immune response. The strong immunogenic nature of both cancer types has contributed to their responsiveness to immunotherapeutic approaches, especially those involving checkpoint blockade with agents targeting PD-1 and CTLA-4. However, the application of PD-L1 inhibitors in the treatment of renal cell carcinoma remains relatively restricted [116].

After the introduction of ipilimumab in 2011 for the systemic treatment of melanoma, immunotherapy has made significant strides in treating both resectable and unresectable melanoma [117]. The CheckMate 037 [118,119]and CheckMate 066 trials established nivolumab's efficacy in patients with metastatic melanoma. Additionally, the KEYNOTE-006 trial, which compared pembrolizumab and ipilimumab for advanced melanoma, showed pembrolizumab's superiority in terms of the 2-year overall survival rate [120].

In the 2023 ASCO Guideline Update on Systemic Therapy for Melanoma, checkpoint inhibitors are positioned as the primary treatment choice for malignant melanoma. They are recommended for neoadjuvant therapy (in resected stage III B-IV melanoma), as adjuvant therapy (for resected stage II B or higher), and for unresectable melanoma. For patients with unresectable or metastatic cutaneous melanoma, or resected stage IV melanoma, the combination of ipilimumab and nivolumab serves as one of the primary treatment options [121].

In selected cases of metastatic kidney cancer, monotherapy with an immune checkpoint inhibitor, such as pembrolizumab, can represent a suitable therapeutic choice, particularly when combination regimens are not indicated or tolerated. However, in metastatic patients whose disease is categorized as intermediate or poor risk and who are suitable candidates for immunotherapy, current clinical guidelines tend to favor starting with a dual-agent immunotherapeutic regimen as the initial line of systemic treatment [122]. Currently, five immunotherapy-based combination treatments have received approval for clinical use. These include the pairing of ipilimumab with nivolumab, pembrolizumab with axitinib, as well as other therapeutic duos such as nivolumab combined with cabozantinib, avelumab administered alongside axitinib, and pembrolizumab used in conjunction with Lenvatinib [123]. Among these, the ipilimumab and nivolumab combination is specifically approved for intermediate- and poor-risk mRCC patients [124].

Despite their efficacy, these agents also cause immune-related adverse effects that may be life-threatening if not detected and controlled appropriately [125].

Targeting the PD-1/PD-L1 immune checkpoint pathway has demonstrated significant therapeutic benefits in patients with advanced or inoperable bladder cancer, including those with metastatic disease. Nivolumab has received FDA approval as adjuvant therapy in individuals with urothelial carcinoma who face an elevated risk of disease recurrence after undergoing surgery. Additionally, the PD-1 inhibitor pembrolizumab was authorized for use in patients whose condition has worsened despite prior treatment with platinum-based chemotherapy, a decision supported by findings from the phase III clinical study known as KEYNOTE-045 [126].

For prostate cancer, the use of angiogenesis and checkpoint inhibitors in therapeutic strategies is limited. Currently, pembrolizumab is the only FDA-approved treatment option, although it has not been approved by the EMA. [127].

Beyond the therapies previously mentioned, each of these pathologies benefits from specific treatments targeting different types of genetic mutations and molecular pathways.

For malignant melanoma with BRAF gene mutations (V600E/K), treatment combinations such as dabrafenib with trametinib (or encorafenib with binimetinib) are indicated [128,129].

In prostate cancer, besides androgen receptor pathway inhibitors, non-hormonal, non-cytotoxic treatments like poly-ADP ribose polymerase inhibitors (PARPi) have emerged, specifically designed to target cancer cells harboring BRCA mutations [130]. While no AKT inhibitors are currently approved, the investigational drug ipatasertib has demonstrated significant activity in clinical trials when combined with abiraterone acetate in patients with loss of the tumor suppressor protein PTEN, as confirmed by immunohistochemistry [131].

CONCLUSION

The link between malignant melanoma and urological cancers is underpinned by common epidemiological factors and genetic mutations, establishing a foundation for progress in personalized medicine. As understanding of the shared molecular pathways in these cancers expands, opportunities for tailored prevention strategies, screening practices, and individualized treatments become increasingly apparent. Identifying genetic predispositions—such as BAP1 and CDKN2A mutations—early on, along with employing targeted therapies and immunotherapies, is expected to meaningfully enhance patient care in the near future.

Personalized medicine holds great promise for patients with elevated risks of both melanoma and urological cancers. By leveraging genomic profiling alongside advancements in immunotherapy and targeted therapies, more tailored and effective treatment options become possible, enhancing patient outcomes. However, ongoing research and clinical trials are essential to fully understand the effects of shared genetic mutations and molecular pathways and to establish comprehensive, individualized treatment protocols. Further refinement in treatment sequencing approaches will also be necessary to optimize care for these patients.

Conflicts of interest and sources of funding

The authors declare no conflict of interest. No artificial intelligence automatically generated text was inserted in this manuscript, and no image was previously published in another journal or is under consideration for publication elsewhere. This research received no external funding.

Authors' contribution

DPH contributed to the manuscript's conceptualization, methodology, discussion, supervision, and writing. MAB contributed to the manuscript's editing, data curation, and writing. NM contributed to the editing and data curation of the manuscript. OSC contributed to the conceptualization, discussion, and supervision of the manuscript. MDV contributed to the manuscript's conceptualization, editing, and data curation. CT contributed to the discussion, data curation, and writing of the manuscript. IA contributed to the methodology, review, and editing of the manuscript. BOF contributed to the conceptualization, discussion, review, and supervision of the manuscript. VMG contributed to the editing, data curation, and writing of the manuscript. OKIM contributed to the conceptualization, discussion, and supervision of the manuscript. CTM contributed to the conceptualization, methodology, investigation, discussion, review, editing, supervision, data curation, and writing of the manuscript.. All authors have read and agreed to the published version of the manuscript.

Ethics approval and consent to participate

The study was conducted under the Declaration of Helsinki. The research was conducted under ethical guidelines and regulations, ensuring compliance with all necessary protocols.

Patient consent for publication

Written informed consent has been obtained from the patient to publish this paper.

Abstract: Multiple sclerosis (MS) is an autoimmune disease in which the myelin sheath is damaged by the body itself. Because of the symptoms and progressive forms, in most cases, patients experience recurrent depressive disorder or anxious depression disorders. Depression treatment for MS patients stands in two categories, one is psychotherapy and the other is pharmacological. This article presents the research results on customized pharmacological treatment schemes applied to a group of relapsing-remitting multiple sclerosis (RRMS) patients with moderate, or severe, depression. All of them are included in the national treatment program for multiple sclerosis and their health state is continuously monitored. The therapeutic scheme based on four different antidepressants had encouraging results, meaning that any of the antidepressants used is efficient and with the patient's good tolerance. There were no side effects that could determine interruption of the treatment. Further research development would focus on improved therapeutic plans for patients with depression disorders in relapsing-remitting multiple sclerosis.

Keywords: depression disorder; therapeutic particularities; multiple sclerosis; HAM-D scale

INTRODUCTION

In 1868, the neurologist Jean-Martin Charcot mentioned for the first time multiple sclerosis (MS) as a neurological affection with unpredictable evolution varying from benign (mild) up to aggressive. This illness especially affects people, aged between 30-50 years, most of them being diagnosed in their mid-thirties. There are also teenagers affected, mostly the ones who smoke and the overweight young women. The official reports [1] mention the ratio of males and females as 1:3.

There is no identified specific factor to trigger MS, so the assumption is that of a series of factors that could cause the disease, like:

- genetic factors - usually, if one parent has a diagnosis of multiple sclerosis, the risk for their children to have MS is about (2 - 3)%, and, more importantly, if both parents have a diagnosis of multiple sclerosis, the risk for their children to have this disease is about (12 - 30)%;

- Environmental factors - are diverse and perhaps complementary, of which the following are considered relevant: prolonged sun exposure during childhood and adolescence - determines high serum vitamin D levels and thus lower risk of MS; smoke from smoking - affects systemic immunity and can damage the central nervous system (CNS); obesity - especially in teenage girls, when hormonal changes that occur secondary to obesity are related to inflammatory processes; sleep disturbance - wake cycle and poor quality of rest; brain trauma - when being a child or adolescent could cause the disease.

Multiple sclerosis is an autoimmune neurodegenerative disease that acts on and destroys the central nervous system [2,3]. It is an inflammatory disease that leads to demyelination and axonal loss, resulting in manifest cognitive, motor, or sensory symptoms such as depression, emotional distress, or anxiety. As mentioned in [4],

the clinical course of MS is classified as follows: Clinically Isolated Syndrome (CIS); Relapsing-Remitting (RRMS); Primary Progressive (PPMS); Secondary Progressive (SSMS).

Once the evolution of MS is on, the predominant emotional disorder is stated to be [5,6] depression. Patients with depression also have a poor psychosocial quality of life, manifest diminished capacity to work, and manifest decreased therapeutic compliance.

Most of the studies [7,8,9,10,11] mention fatigue, depression, and pain as inherent disorders associated with structural and functional changes in the brain in MS. These changes have been noticed in the basal ganglia, prefrontal cortex, and limbic system [12,13,14].

Comorbid fatigue and/or depression symptoms reported in patients with MS are also linked to impairment of the hypothalamic-pituitary-adrenal (HPA) axis [15]. Because chronic fatigue and depression are low levels of cortisol and dehydroepiandrosterone (DHEA) it is possible to be endocrine contribution. Studies [16,17] have proved that MS patients state to have increased energy after taking corticosteroids as treatment for MS relapse.

As mentioned in [18,19] depressive disorder (MDD), or clinical depression, represents a debilitating disease exhibiting at least one major depressive episode for at least two weeks, with an evident bad mood, low interests and pleasure (anhedonia), poor cognition and neurovegetative symptoms (fatigue, loss of appetite, insomnia). There is a high focus on improving the quality of life for MS patients. Depression treatment usually is individualized and is split between associated pharmacological and non-pharmacological ones.

The pharmacological treatment with Desipramine (tricyclic antidepressant) 200 mg/day [20] and Paroxetine (selective serotonin reuptake inhibitor) 40 mg/day [21] is mentioned in comparison with placebo, for a period of five and, respectively, twelve weeks. As a result, there was noticed a slight improvement of depression symptoms but, not a statistically significant result.

In [22] it is analyzed how a specialized exercise training program with prescriptive guidelines [23, 24] having as background the social cognitive theory sustains the reduction severity of depressive symptoms in MS patients.

This article presents the research results on therapeutic particularities of depression, a survey carried out on a group of relapsing-remitting multiple sclerosis (RRMS) patients with moderate, or severe, depression forms. The therapy plan was developed based on the authors' expertise in the treatment of multiple sclerosis and mainly consists of the administration of one of the following antidepressants: venlafaxine; sertraline; mirtazapine; and trazodone. The diagnosis and the severity of depression were evaluated by the total Hamilton Depression Rating Scale (HAM-D).

Aspects of materials and methods used in research, as well as results, discussion, and conclusion of the obtained results, are evidenced in the next chapters. Further research development focus is also mentioned.

MATERIALS AND METHODS

There are different signs of multiple sclerosis [25,26] caused by the location and severity of the myelin sheath lesions. Troubles in moving arms or legs, disorders in equilibrium, visual disturbances, or, when severe, loss of ability for independent motion - these are the alarm signals for this illness.

For the moment, there is no specific and targeted treatment for curing MS, but there are therapeutic schemes usually focusing on fast and high recovery from attacks, reducing probabilities of relapse, slowing down the disease progression, and adequate managing of symptoms. There are also cases when the symptoms are mild and patients do not need specific treatment.

While MS attacks are on, for reducing inflammation of the nerves are used intravenous corticosteroids. If there is no positive response to corticosteroids and the symptoms are extremely severe, plasma exchange can be used for ease of symptoms (not for curing). There are also treatment schemes for lowering the rate of relapse and reducing the risk of brain atrophy, such as immunomodulatory medication, monoclonal antibodies, or antihistamines. Solutions for MS symptom relief are various and customized on patients, like: kynetotherapy to increase muscle strength; muscle relaxers for reducing pain in muscle rigidity; specific medication against pain, insomnia, and depression; and psychological counseling.

There is a common opinion regarding the risk of immobilization for patients with multiple sclerosis but, the highest risk for them is that of suicide. Psychological manifestations have been noticed since the 19th century [27], once the clinical signs of this illness have been described.

About 50% of patients with multiple sclerosis exhibit at least one depression symptom, and a percentage varying in-between (15 ÷ 30)% of these patients have severe depression disorder.

A comprehensive study [28] indicates that the majority of MS patients present with both anxiety and depression symptoms. However, due to the presence of multiple overlaps in diagnostic criteria, it is challenging to ascertain the exact frequency of each of these conditions. The predominant feature of their syndrome points towards depression, anxiety, or, mixed anxiety-depressive disorder. Even for now, it has not been identified yet a direct relationship between multiple sclerosis and depression, the main mechanisms are assumed to be the ones that follow:

- Depression is determined by the process of damaging specific brain zones, related to the control and manifestation of emotions. There are also immune and endocrine changes induced by MS that could determine bad mood feelings.

- Depression is triggered by the emotional impact of the patient when finding out the medical diagnosis of multiple sclerosis.

- Depression manifests as a side effect of pharmacological treatment, like interferon-based medications or corticosteroids.

The criteria for diagnosis of depression, as mentioned by the Diagnostic and Statistical Manual of Mental Disorders, DSM-5 [27] are evidenced in Table 1.

Table 1: Criteria of depression by DSM-5 [26]

No.	Criteria	Tick √ if YES within two weeks
1	Mood of depression - long time a day, almost every day	
2	Diminished interest/pleasure in most activities - long time a day, almost every day	
3	Significant weight loss/gain without specific dieting	
4	Slow down in decision-making and performing physical activities (relevant to the others)	
5	Fatigue and poor energy	
6	Bad feelings and guilt for most of the things done - almost every day	
7	Difficulty in concentration and thinking, indecisiveness - almost every day	
8.	Repeated thoughts of death, suicidal behavior	

An individual is diagnosed with depression if, at least, five of the above symptoms are exhibited within two weeks and one of them should be depressed mood and/or diminished interest or pleasure. Attention is to be given so that symptoms do not result from any substance abuse.

There are also two additional specifiers for the diagnosis, of depression:

- with mixed features – such as manic symptoms;

- with anxious distress – the presence of anxiety symptoms;

The depression causes are multiple and commonly classified in four main categories (A ÷ D), as follows:

A. Psychosocial stress - that represents the disability in MS because it is generated by: global physical impairment; illness evolution in pus, with no possible estimation in time; motor deficits; diminished social role / inadequate support from the family.

B. Neuro-immune-endocrine triad (see figure 1) - as in MS patients the severity of depression depends directly on the amount of cytokines, IFN⍰. In this research, there was noticed decrease in IFN⍰ amount after antidepressant treatment, once the depression symptoms diminished. The cytokines stimulate the axis: HHA (hypothalamic-hypophyseal-adrenal) ⍰ CRH (Corticotropin-releasing hormone) ⍰ ACTH (Adrenocorticotropic hormone) ⍰ CORTISOL. The cytokines disturb the metabolism of monoamines (serotonin, non-adrenaline, dopamine) by prostaglandins - in cerebral areas highly important for depression: the hippocampus and hypothalamus.

C. Relationship between brain injuries and depression - based on neuroimaging evidence (RMN). Multiple sclerosis illness does affect myelin and nerve conduction so depression could be a direct consequence of the disease. The severity of depression directly depends on the right temporal lesions of the frontal lobe and the area adjacent to the basal ganglia.

D. Pharmaceutical treatment - there is no relevant evidence of increased occurrence of depression symptoms caused by the MS pharmacological treatment. Mainly, if the depression gets worse it is caused by the worsening of disability. Depression treatment for MS patients stands in two categories, one is psychotherapy and the other is pharmacological. Psychotherapy commonly consists of: psychological counseling; support therapy and cognitive-behavioral techniques.

To diminish depression, there are some additional steps [29] that could be done by multiple sclerosis patients, complementary to psychotherapy and pharmacological treatment, such as:

- physical exercises - that determine higher endorphins rate and, as a consequence, reduce fatigue and better mood;

- stress management program - meditation;

- talk about feelings and emotions - to a friend, family member, or, priest;

- belong to a community - to take part in targeted activities (walks, talks, reunions);

- find something that makes you happy and enjoy the day;

- help other people in need - get a sense of worthiness and utility;

- pet adoption - if possible and allowed by doctors;

- excellent sense of humor.

Figure 1: Neuro-immune-endocrine triad scheme

IMMUNOLOGICAL FACTORS
• ↑ proinflammatory cytokines
$(Il_6, IFN_\gamma, Il_{1\beta}, TNF_\alpha)$
ENDOCRINE FACTORS
• HHA system activity
CRH
ACTH
CORTISOL

In this research the focus is not on either psychotherapy, or additional actions, even the patients in the sample group also practiced some of these therapies. This research is focused on the therapeutic particularities of depression, in relapsing-remitting multiple sclerosis (RRMS) patients.

Pharmacological treatment in depression for relapsing-remitting multiple sclerosis patients is evidenced in Table 2. These therapeutic schemes are particularly used in neurology clinics the authors work. All the patients of the survey are included in the national program for the treatment of multiple sclerosis and monitored by: neurological examination; brain imaging; psychological examination; and psychiatric examination.

Table 2: Pharmacological treatment in depression

Class	Representative	Dose [mg/day]	Comments
ADT (antidepressants)	Nortriptyline Desipramine	50 ÷ 200 100 ÷ 300	- limited use because of anticholinergic side effects (dry mouth, constipation, urinary and cardiovascular disorders)
SSRI (selective serotonin reuptake inhibitors)	Sertraline Fluoxetine S-Citalopram	50 ÷ 200 20 ÷ 80 10 ÷ 20	- good tolerance; - efficiency; - side effects (sexual dysfunctions, insomnia)
NaSSA (noradrenergic and specifically serotonergic antidepressants)	Mirtazapine	15 ÷ 45	- efficiency; -minimum effects on sexual function; - side effects (weight gain, drowsiness)
SARI (reuptake inhibitors and serotonin 2A antagonists)	Trazodone	150 ÷ 300	- efficiency; - minimum effects on sexual function; - side effects (drowsiness, orthostatic hypotension)
NDRI (noradrenaline and dopamine reuptake inhibitors)	Bupropion	150 ÷ 400	- efficiency; - minimum effects on sexual function; - side effects (convulsions, psychotic symptoms)
SNRI (serotonin and noradrenaline reuptake inhibitors)	Venalafaxine	75 ÷ 225	- efficiency; - side effects (intestinal disorders, psychotic symptoms, arterial hypertension)

The patients in the research group were diagnosed and subsequently admitted to the hospital when acute attacks occurred. Because of the relapsing attacks, patients develop anxious depressive disorder with panic attacks. Once the severe symptoms were relieved, they were discharged from the hospital and followed up the therapeutic scheme so that to get into the survey.

Initially, it was considered for the study a group of 102 patients, registered within a period of 4 years (2019 - 2023). Because of changes in their health conditions, mental and willingness to take part in the study, not the least family involvement, some of them had to retire. So, the size of the study (sample) group got down to 58, but its size remains fit for a research study (as the sample size is greater than 30).

The survey group is made of 58 relapsing-remitting multiple sclerosis patients with moderate, or severe, depression, out of which 18 are males with ages in between 18 and 30 years. The others are 40 females with ages between 30 and 40 years.

One can notice the higher percentage of females with MS diagnostic (40 out of 58, meaning around 69%) aspect revealed by most of the specific literature references. There has to be mentioned the fact that young people (above 25 years old) usually suffer from anxiety or anxious depression disorder, while mature people suffer from anxious depression disorders or recurrent depressive disorders. The survey period lasted for 16 weeks.

The customized therapeutic scheme applied for diminishing depression, based on the authors' expertise in the diagnosis and treatment of (relapsing-remitting) multiple sclerosis consists of the administration of one of the antidepressants (see Figure 2):

- venlafaxine - for 7 patients (12%), in flexible dosing of 75 ÷ 150 mg/day;
- sertraline - for 8 patients (14%), in flexible dosing of 50 ÷ 100 mg/day;
- mirtazapine - for 19 patients (33%), in a dose of 30 mg/day;
- trazodone - for 24 patients (41%), in a dose of 150 mg/day;

The selected percentages for medication considered the medical history of patients and estimated positive effects of the antidepressant. Also, previous experience of the authors (medical team) in the administration of these types of medicines is important. If there are multiple relapsing attacks, an increase in dosage has to be considered.

The antidepressant medication has to be administrated only in consideration of the following rules (see Figure 3):

- the patients who do not exhibit hypnic jerk were administered sertraline or venlafaxine which do not have sedative effects;
- the patients with hypnic jerk were administered mirtazapine or trazodone, as they also have sedative effects;
- the patients with appetite decrease/weight loss were administered mirtazapine.

Figure 2: Schematic representation of the depression medication for RRMS patients

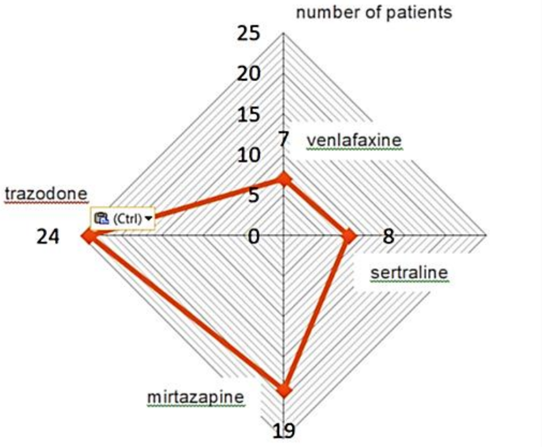

Figure 3: Customized therapeutic plan for RRMS patients

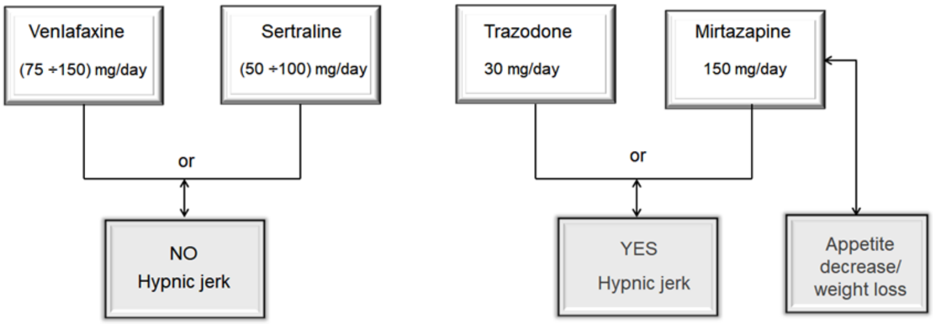

RESULTS

In diagnosing depression among patients with relapsing-remitting multiple sclerosis, it's essential to apply DSM-5 criteria tailored for MS. Recent guidelines from the National Multiple Sclerosis Society (2025) highlight the interplay between neurological symptoms and psychological distress in MS. These updated guidelines advocate for a nuanced diagnostic approach beyond traditional tools like the Hamilton Depression Rating Scale (HAM-D), ensuring diagnoses reflect current clinical insights.

This scale is a multiple-item questionnaire, providing a self-evaluation tool for depressive symptoms. The advantage of using HAM-D is that of high fidelity [30] in terms of clinical symptom assessment due to multiple questions for most of the items. It is compatible with DSM and provides an indicator for the severity of depression reported by an adult, based on a threshold score of clinical value.

Some relevant aspects of HAM-D and its scores are mentioned [31,32] next:

- the scale is scored between 0 and 4;

- scores of 0–7 suggest normal state;

- scores of 8–16 suggest mild depression;

- scores of 17–23 suggest moderate depression;

- scores starting from 24 suggest severe depression.

Before starting the customized depression disorder therapeutic schemes, based on the HAM-D test results, patients were divided into five groups, depending on test scores, as follows:

- 14 patients with HAM-D = 25 (group 1, G1);

- 5 patients with HAM-D = 21 (group 2, G2);

- 22 patients with HAM-D = 19 (group 3, G3);

- 14 patients with HAM-D = 18 (group 4, G4);

- 3 patients with HAM-D = 17 (group 5, G5).

Survey and evaluation after two weeks of treatment proved the improvement of depression symptoms, evidenced by psychiatric examination and HAM-D scores. The same trend was evidenced by further evaluation after six weeks of treatment, as evidenced in Figure 4). One can notice that patients with a HAM-D score of 25 at the beginning of the survey (severe depression, group G1) got to a score of 19 (moderate depression) after 2 weeks of treatment and, further, achieved a score of 11 (mild depression) by the end of the survey (within 6 weeks of therapeutic scheme applied). The same improvements in HAMD-D scores are observed for the patients classified in the other four groups (G2-G5).

Figure 4: HAM-D scores for RRMS patients after the therapeutic plan

	G1	G2	G3	G4	G5
🟥 initial	25	21	19	18	17
🟨 after two weeks	19	17	16	16	14
🟩 after six weeks	11	9	12	9	9

DISCUSSION

There are different signs of multiple sclerosis caused by the location and severity of the myelin sheath lesions. Some alarm signals for this illness are: disorders in equilibrium, visual disturbances, and loss of ability for independent motion.

There is a common opinion regarding the risk of immobilization for patients with multiple sclerosis but, the highest risk for them is that of suicide. Depression represents a real problem in patients with multiple sclerosis, with about 50% of them exhibiting at least one depression symptom.

This research study is focused on therapeutic particularities of depression, in patients with relapsing-remitting multiple sclerosis (RRMS). Even though the patients in the sample group previously practiced either psychotherapy or additional actions for healing depression, the results did not prove to be fundamentally encouraging.

In the sample group, there are 18 males - from 18 up to 30 years old and 40 females aged between 30 and 40 years. This proves the higher percentage of females having the diagnosis of multiple sclerosis.

Depression disorder diagnostic was given to the 58 sample patients based on psychiatric and psychological examination by the total Hamilton Depression Rating Scale. There were considered five groups, depending on HAM-D test scores, all pointing toward severe to moderate depression disorders. The patients are included in the national program for the treatment of multiple sclerosis.

Analyzing the obtained results, important aspects of therapeutic schemes are evidenced. First, it is obvious that any of the four antidepressants are efficient and with patients good tolerance. Surveys and evaluations after two weeks of treatment proved the improvement of depression symptoms. The same trend was evidenced by further evaluation after six weeks of a customized therapeutic scheme.

Then, it is to be emphasized the lack of side effects that could determine interruption of the treatment. None of the sample group patients showed relevant side effects.

After two weeks of treatment, the HAM-D scores turn from severe depression up to moderate depression (for groups G1, and G2) and from moderate depression to mild depression (groups G3, G4, G5). After 6 weeks of the therapeutic scheme applied, in each of the groups, the result was that of mild depression.

The variation of HAM-D scores, through the survey, for each of the groups, G1-G5, is evidenced in Figure 5. Regression models (dash lines) that fit the survey data (curved lines) are marked along each of the regression lines, just to prove the tendency (by the negative slope) of decreasing the HAM-D results.

Statistical processing of data resulted in mean values of HAM-D scores as follows: 20.28 when starting the survey (initially); 16.69 after two weeks of customized therapeutic scheme and 10.67 at the end of the survey (after 6 weeks), as evidenced in Figure 6. It can be noticed that the trend was that of decreasing HAM-D scores so that the patients' symptoms of depression turned from moderate depression (scores of 17–23) to mild depression (scores of 8–16).

Figure 5: HAM-D models during the survey

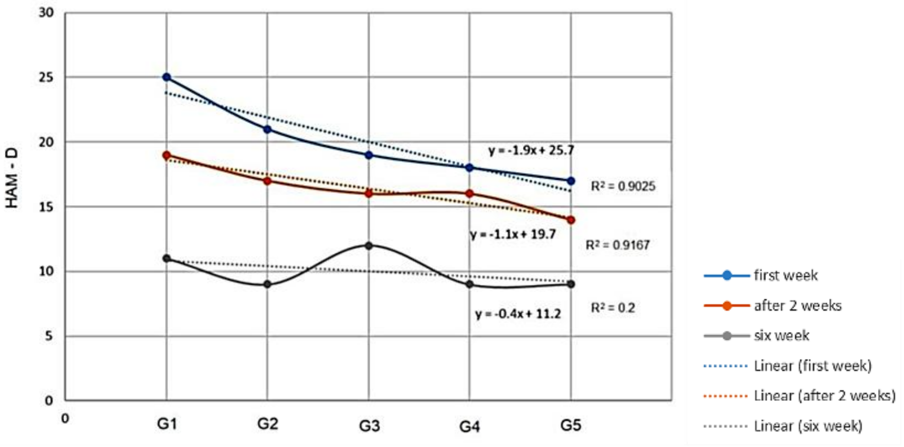

Figure 6: HAM-D mean scores

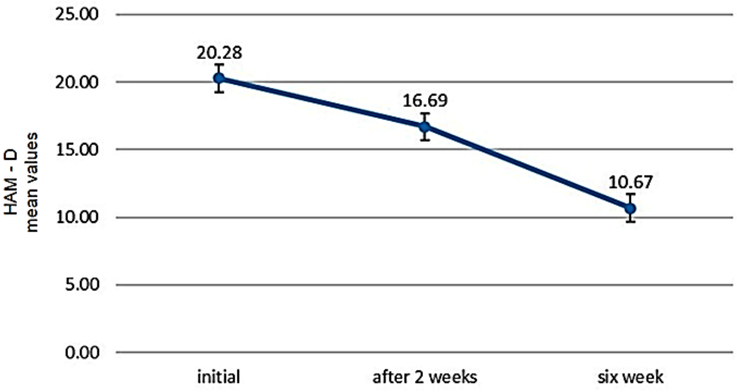

The items of the HAM-D scale that target somatic aspects (psychomotor retardation, agitation, depth of sleep, wake-up insomnia) are less specific when evaluating depression and anxious depression in patients with associated relapsing-remitting multiple sclerosis.

CONCLUSION

Depression is, relatively, common in MS patients, with approximately half of them being diagnosed with it. There is no exact knowledge of its relevance but it is assumed the influence of many factors like: psychosocial, immunological, and brain injuries. It is not sure if some MS patients have depression as a multiple sclerosis reaction or if depression is part of this illness's biology.

Many times, depression is underdiagnosed in MS patients because some of the depression symptoms also belong to the disease (fatigue, concentration difficulties, psychomotor slowness, sleep disorders, sexual disorders).

There is a negative relationship between multiple sclerosis and depression, as depression can be a factor for worsening MS and reverse. Most of the MS patients exhibit both anxiety and depression symptoms, the predominant feature of their syndrome being the one that points towards depression, anxiety, or, mixed anxiety-depressive disorder. The depressive symptoms are in remission with adequate treatment (psychotherapy and/or pharmacological) thus improving the quality of patient life.

Depression treatment for MS patients stands in two categories, one is psychotherapy and the other is pharmacological. Additionally, these, complementary actions could be performed by the patients as, for example: doing things that make them happy, activating a stress management program, belonging to a group of people that share similar problems, etc.

The research results on therapeutic particularities of depression are presented in this article. The sample group used in the study is made of 58 patients with relapsing-remitting multiple sclerosis, out of which 69% are females. They are between 18 to 40 years old.

The customized therapeutic scheme developed is based authors' expertise in the treatment of relapsing-remitting multiple sclerosis and mainly consists of the administration of one of the following antidepressants: venlafaxine; sertraline; mirtazapine; trazodone. The antidepressants are prescribed only considering particularities of the patient's health, like: exhibiting or not exhibiting hypnic jerk; evidence of appetite decrease, or weight loss.

The diagnosis and the severity of depression were evaluated by the total Hamilton Depression Rating Scale (HAM-D). Periodic evaluation of patients' depression symptoms evidenced improvement from severe to moderate to mild depression, after two weeks and, respectively, six weeks of therapeutic scheme.

Further research development would focus on different treatment schemes for depression disorders in MS patients, as well as on psychotherapy and sustained family involvement. It would also be pay attention to the complementary/additional steps in depression customized treatment as: stress management program - meditation; belonging to a community - so that to take part in targeted activities (walks, talks, reunions); find something that makes happy and enjoy the day; help other people in need - gets a sense of worthiness and utility.

Maybe, more adequate screening could be done using the Beck Depression Inventory (BDI) as it does exclude the items on somatic symptoms. It was not used in this research as the clinic where the survey was developed did not commonly apply the inventory for assessing depression severity.

Finally, it could be stated that a customized therapeutic scheme for depression disorders in patients with multiple sclerosis is considered to be the main tool for reducing symptoms and improving, even if possible, eliminating the depressed mood.

Conflicts of interest and sources of funding

The authors declare no conflict of interest. No artificial intelligence automatically generated text was inserted in this manuscript, and no image was previously published in another journal or is under consideration of being published elsewhere. This research received no external funding.

CLINICAL PRACTICE

Papillary thyroid carcinoma arising on a hypertrofic pyramidal lobe

Rodica Petris[1], Ionut B. Sandu[1], Adina Dragomir[1], Dumitru Ioachim[1], Cristina Iosif[2], Ruxandra Dănciulescu-Miulescu[3], Alexandra Mirica[3], Diana Paun[3]

INTRODUCTION

Development of thyroid gland starts by the pharyngeal epithelium thickening floor which later forms a diverticulum which, in its development is pushed caudally. The descent path is usually anterior to hyoid bone but it can also be posterior or through the hyoid bone and ends on the anterior surface of the first few tracheal rings.

This primitive steam that connects primordium with pharyngeal floor becomes thyroglossal duct. Until the second month of gestation thyroglossal duct devolve, leaving at its place a small lump – the foramen cecum, at the unification of third medium with posterior third of the tongue, but portions of the duct associated with thyroid tissue can persist at any site between tongue and thyroid [1, 2].

Cells in the lowest portion of the thyroglossal duct which comprises normal thyroid tissue differentiates in forming pyramidal lobe of the thyroid gland. Pyramidal lobe often comes out from the thyroid isthmus, but can also come from the medial side of one or both thyroid lobes [1]. The pyramidal lobe is thought to be present in 15-75% of the general population [1, 3]. Thyroglossal duct fails to involute in approximately 7% of the population [4].

Many remnants of thyroglossal duct are never detected clinically (2) and malignant transformation is uncommon [5].

CASE REPORT

We present the case of a 50 years old female patient with chronic renal failure of unknown etiology (probably secondary to hyper blood pressure), with Graves Disease (in treatment with antithyroid drugs for about 1 year) who was admitted in our department after she has initially presented in an ENT department (Otolaryngology) for the investigation of a tumoral mass located in the midline upper neck. At that moment physical exam revealed a 2/3 cm mass between the hyoid bone and the thyroid cartilage, mobile on swallowing, painless spontaneously and on palpation, covered by normal skin. IRM exam revealed a bilobate lesion 2.9/1.1 cm, very well encountered, in close relationship with the adjacent muscles and the hyoid bone, without any other pathological changes on the structures of the anterior neck: no enlarged lymph nodes. There were no reference about thyroid gland on the IRM report. The IRM conclusion was: expansive anterior cervical soft tissues tumoral mass. Surgical excision of the tumoral mass and simultaneous removal of the central portion of the hyoid bone (Sistrunk procedure) was performed and the pathology report showed papillary thyroid carcinoma arising from thyroglossal duct. In our department, three months later, thyroid ultrasound showed hypoechoic, inhomogeneous echotexture suggestive for chronic autoimmune process, hypoechoic nodule with discrete Doppler flow, without hypoechoic halo located at the connection of the right thyroid lobe with isthmus and two micro lymph nodes with intense Doppler flow, without hilum of 0.5/0.4 cm and 0.7/0.4 cm located anterior of the larynx. Tumoral mass previously removed in the ENT department was reviewed and the pathology report showed tumoral multilobulated pyramidal thyroid lobe with pattern

[1] C.I. Parhon National Institute of Endocrinology, Bucharest, Romania
[2] St Maria General Hospital, Bucharest, Romania
[3] Carol Davila University of Medicine and Pharmacy, Bucharest, Romania

of solid and sclerosant variant of papillary carcinoma, infiltrative into fibro conjunctive, adipose and muscular adjacent tissue (Figure 1 and Figure 2) and areas of micro angioinvasion of the capsule (Figure 3).

Figure 1: Papillary carcinoma infiltrative into fibroconjunctive, adipos and muscular adjacent tissue (x20 HE)

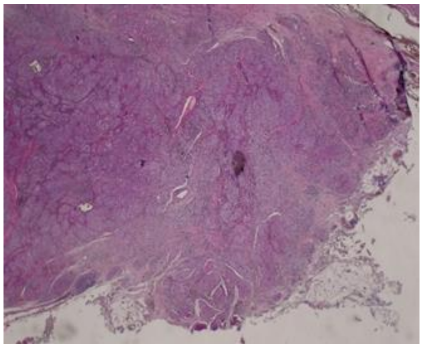

Figure 2: Papillary carcinoma infiltrative into fibroconjunctive adipose and muscular adjacent tissue (x40 HE)

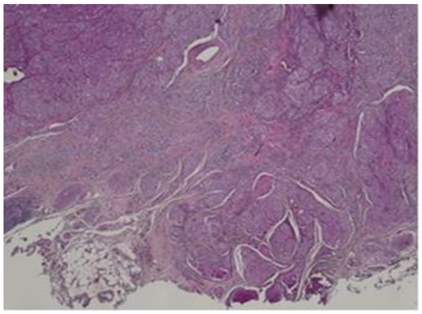

Figure 3: Micro invasion of the capsule (x200 HE)

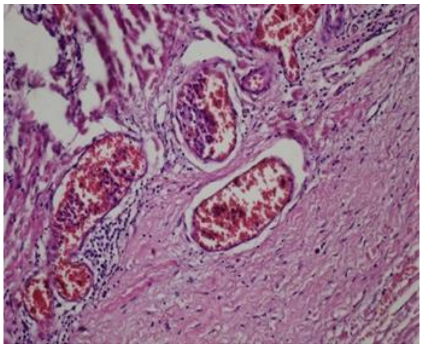

In this context, we decided total thyroidectomy (also as a treatment for Graves Disease) with dissection of central lymph nodes compartment. Histopathology report revealed embedded thyroid isthmus focus of papillary thyroid carcinoma 0.7/0.6 cm with tumoral pattern similar to that of tumoral pyramidal lobe previously removed (Figure 4), with areas of marginal invasion of the capsule (Figure 5) and micro angioinvasion of the capsule (Figure 6). The pathology report also showed reactive lymphadenopathy and post surgery staging was pT3N0.

Figure 4: Embedded thyroid isthmus focus of papillary thyroid carcinoma (x20 HE)

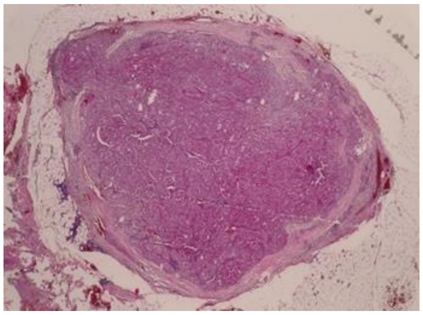

Figure 5: Marginal invasion of the capsule (x100 HE)

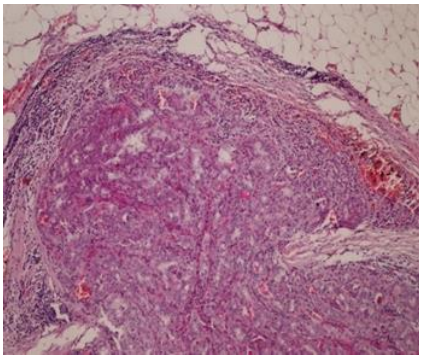

Figure 6: Microangioinvasion of the capsule (x100 HE)

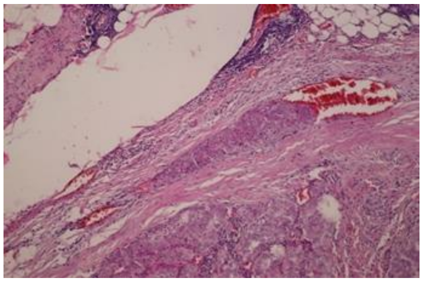

Radioactive iodine therapy was decided. Postsurgery, thyroglobulin level after Levothyroxine withdrawal is 0.2 ng/ml with unmeasurable thyroglobulin antibodies and 50 mCi 131I was administered. Post ablation thyroid scan showed no uptake of 131I in the thyroid bed or elsewhere in the body. Because of the association of BRAF mutation with papillary carcinoma of the pyramidal thyroid lobe, genetic testing of BRAF gene were performed and they were negative for somatic mutations in the 600 codon.

DISCUSSION

The detection of a pyramidal lobe or a thyroglossal duct in patients with hyperthyroidism is indicative of autoimmune hyperthyroidism. The vestiges of thyroglossal tract are more often seen in patients with Graves Disease compared with patients with autonomously functioning thyroid nodules and this is related with the presence of stimulating thyrotropin receptor antibodies [6, 7]. Pyramidal lobe can be the primary or secondary site of thyroid malignancy and during thyroidectomy, total excision of the pyramidal lobe is essential for patients with thyroid cancers who undergo radioactive iodine treatment (RAI) because the presence of pyramidal lobe prevents the increase in TSH and absorbs a large amount of the isotope and thus decrease the possibility to benefit from the treatment [8-10]. Residual pyramidal lobe can harbor cancer cells and from this point of view its total excision is indicated in thyroid cancers. In case of probable recurrence of malignant diseases due to pyramidal remnants, scintigraphy, ultrasound of the neck, computed tomography are indicated [11-13]

Thyroid pyramidal lobe can be the origin or recurrent site of papillary thyroid carcinoma. Malignant tumors arising from pyramidal lobe are rare and are associated with a high rate of concurrent thyroid cancer and it must be differentiated from thyroglossal papillary cancers because pyramidal cancer requires orthostatic thyroid surgery which is not always necessary in papillary thyroglossal cancers [14, 15]. Pyramidal lobe tumors are associated with poor prognostic factors such as: extra thyroidal extension, advanced T-stage, cervical lymph node metastasis, advanced AJCC stage (III, IV), BRAF mutation, multifocal thyroid cancer [16, 17]. In our patient there was one single embedded thyroid focus, no local lymph nodes metastasis and no distant metastasis. BRAF mutation was negative.

Malignant tumors arising from thyroglossal duct are also rare [18]. The majority are papillary carcinomas (about 94%) and less than 5% are squamous carcinoma [19]. The Sistrunk procedure that implies the simultaneous removal of the central portion of the hyoid bone to ensure the complete removal of the thyroglossal tract is enough for thyroglossal squamous carcinoma although they have a poor prognosis and a mortality rate of 30-40% [20]. On the other hand, papillary thyroglossal carcinomas are multicentric and multifocal and total thyroidectomy followed by 131I ablation and thyroid-stimulating hormone suppression is often required. There are still controversy regarding the need for total thyroidectomy, central or lateral compartment neck dissection and I131 ablation therapy in cases of papillary carcinoma of thyroglossal duct [21]. The decision depends on: tumor size (tumors larger than 1 cm require total thyroidectomy), abnormal findings of thyroid (multinodular goiter, cold nodule in a thyroid iodine uptake), histopathological findings, and the presence of enlarged lymph nodes or a history of neck irradiation [22].

In conclusion: in this report we have described a papillary thyroid carcinoma arising from a multilobulated pyramidal lobe including from a nodular peri-isthmic remnant of the pyramidal lobe (secondary to incompletely resected anterior tumor of the isthmus), in a patient with Graves Disease. The rest of the thyroid parenchyma is non tumoral. The complete resection of the thyroid is necessary because of tumor aggressiveness and the necessity of radioiodine ablation therapy.

Atypical Cogan syndrome; case report

Gabriela C. Musat[1,2], Roxana E. Decusara[2], Ovidiu Musat[3]

Abstract: *Cogan syndrome is a rare disease characterized by the concomitance of non-syphilitic interstitial keratitis with Meniere-like vestibulo-auditory symptoms. There are criteria for the diagnosis of both typical and atypical Cogan syndrome. We present the case of a 40 years old woman with sudden onset of hearing loss, tinnitus, intense vertigo, instability associated with kerato-conjunctivitis. The concomitance of the symptoms, the onset, and the evolution under treatment are consistent with the diagnosis of atypical Cogan syndrome.*

Keywords: *Cogan syndrome, atypical Cogan syndrome; vertigo; hearing loss*

INTRODUCTION

Cogan syndrome is a disorder characterized by the association between the Meniere-like vestibulo-auditory symptoms and ocular symptoms (interstitial keratitis). Although the first to describe a disorder associating ocular and inner ear symptoms were Morgan RF, Baumgartner in 1934 [1], the name of the disease comes from Dr. David Cogan who published in 1945 a series of 4 cases of patients with non syphilitic interstitial keratitis and vestibulo-auditory symptoms [2]. In 1980 Haynes et al proposed the enlargement of the criteria for the diagnosis, defining typical and atypical Cogan syndrome. They proposed that other ophthalmologic inflammatory manifestations such as episcleritis, uveitis, conjunctivitis, can be considered as disease criteria for atypical syndrome. [3]

For a disease described such a long time ago there is very little knowledge about the etiology of the disorder. Until now, approximately 250 cases have been published but we still don't understand the etiopathogeny of the disease. It is considered an autoimmune disorder. This disease seems to affect young Caucasian adults with ages ranging between 25 to 35 years old, in most of the cases. [5]

CLINICAL FEATURES

Ocular manifestations: The main characteristic of the disease is the ocular involvement. Usually patients have red eye, eye pain and photophobia. The typical Cogan syndrome is defined by the presence of the non syphilitic interstitial keratitis. The examiner might notice granular and irregular infiltrate on the posterior part of the cornea. Neovascularization is also a possibility. Blindness and amaurisis can happen but usually the lesion regresses and the loss of visual acuity is moderate. In the majority of the cases both eyes are affected, the unilateral disease is infrequent [6]. In the atypical Cogan syndrome the vestibulo-cochlear manifestations can be associated with scleritis, episceritis, uveitis, optic neuritis, conjunctivitis or glaucoma. [7]

Vestibulo-cochlear symptoms: Cogan syndrome is classically characterized by sensory-neural hearing loss, vertigo and

[1] St Maria General Hospital, Bucharest, Romania
[2] Carol Davila University of Medicine and Pharmacy, Bucharest, Romania
[3] Carol Davila University Emergency Central Military Hospital, Bucharest, Romania

tinnitus in an association that resembles to Meniere's disease. The hearing loss might be profound, leading to cophosis in almost 52% of cases and usually it is bilateral. The auditory deficit is installed in days, months, too slow for a sudden nerosensorial hearing loss and too quick for a presbyacusys. The speech discrimination scores are poor. The hearing loss is associated with tinnitus. [4]

The vertigo can be important causing marked instability, ataxia, sometimes associated with nausea and vomiting. The nystagmus can be observed at the ocular examination. In most of the cases, complains are similar to Meniere's disease.

Other signs and symptoms

General manifestations of the disease are not rare, fever has been reported in many cases, weight loss and extreme asthenia can be found in patients with Cogan's.

Cardiac involvement, especially aortic insufficiency is present in as much as 15% of cases. Large vessels can also be affected causing heart murmur, abdominal pain, claudication of the members.

Musculo-scheletal involvement manifests as myalgia or arthritis (mono, oligo or polyarthritis).

Neurological signs appear in ¼ of cases [8], patients might have paresis, hemiplegia, aphasia, cerebellar syndrome, pyramidal syndrome, spinal cord disorders, epilepsy, and vigilance disorders. MRI can sometimes detect lesions of the white matter consistent with cerebral vasculitis.

Cutaneous lesions might appear during attacks taking the form of urticarial rash, vascular purpura, ulcerations or nodules.

Some patients might have gastro-intestinal or pulmonary symptoms.

Laboratory investigations

Biologic parameters can be modified in Cogan syndrome, especially during the attacks, but no laboratory test in pathognomonic for the disease. Leukocytosis, elevated ESR, anemia, hyperfibrinemia may appear. Several immunelogical modifications also can be noticed: rheumatoid factor, antinuclear antibodies, cryoglobulins, lupus anticoagulant but none of these are specific or relevant for the disease. [9]

In small series of patients, some authors determined the presence of specific antibodies for the inner ear or cornea but these studies were not relevant and could not be reproduced by other authors so cannot be used to support the diagnosis of Cogan.

Differential diagnosis

The first differential diagnosis one should bear in mind when facing a rapid onset hearing loss with vestibular symptoms and interstitial keratitis is syphilis. Another important differential diagnosis is Meniere's disease but in this case the ocular manifestations are absent.

Another diagnosis to be differentiated from Cogan is Susac syndrome, a retino-cochleo-cerebral vasculopathy involving the arterioles, manifested by central neurological disorders, visual acuity loss, and hearing loss.[10] Vogt- Koyanagi-Harada syndrome is characterized by uveitis, alopecia, vitiligo and audio-vestibular symptoms.[11] . Other systemic diseases such as Wegener granulomatosis, PAN, relapsing polychondritis, Behcet disease, and Sjogren syndrome can associate vestibulo-auditory symptoms with ocular involvement.

Evolution, prognosis

In some cases, the onset of the disease is preceded by upper respiratory tract viral infection.

The vestibular and auditory symptoms can be the first manifestations of the disease in 41% of cases. in 43 % of cases the Cogan syndrome debuts with the ocular symptoms. The involvement of the two organs is usually done in approximately 3 months [8]. In cases of atypical Cogan syndrome the complete symptomatology might be installed in a long period, even years.

Usually, after the first attack the disease enters a phase of remission without evident symptomatology. There is a possibility that there are recurrent episodes that repeat at variable intervals. Once installed the hearing loss is not remissible. The vestibular symptoms diminish as a result of the compensation mechanisms. The ocular symptoms have a variable evolution, but usually respond favorably to treatment.

Treatment

As the etiology and the pathogenic mechanisms are not known, there is not yet available a codified treatment for Cogan's syndrome.

Usually the first line of treatment is represented by corticosteroids. [12] In cases where the corticodependence is installed or in cases of corticoresistance there is the possibility of using other therapeutic agents such as immunosupressants (cyclophosphamide, azathioprine, and methotrexate). [13] The corticotherapy should be prescribed in high dosage (1-1.5 mg prednisone or equivalent) and interrupted in two weeks in cases where it is ineffective. Studies show that the vestibulo-cochlear symptoms respond to treatment only in one third of the cases (orphanet). Once the deafness is installed, it is usually non-reversible.

In the last years there were attempts to treat Cogan syndrome with TNF alfa blockers but there are not enough evidence based results [14, 15]

CASE REPORT

We present the case of a 40 years old woman with no remarkable medical history who presented at the emergency department of our hospital accusing sudden onset intense vertigo and dizziness, tinnitus and hearing loss in the right ear. The patient was admitted in the ENT department.

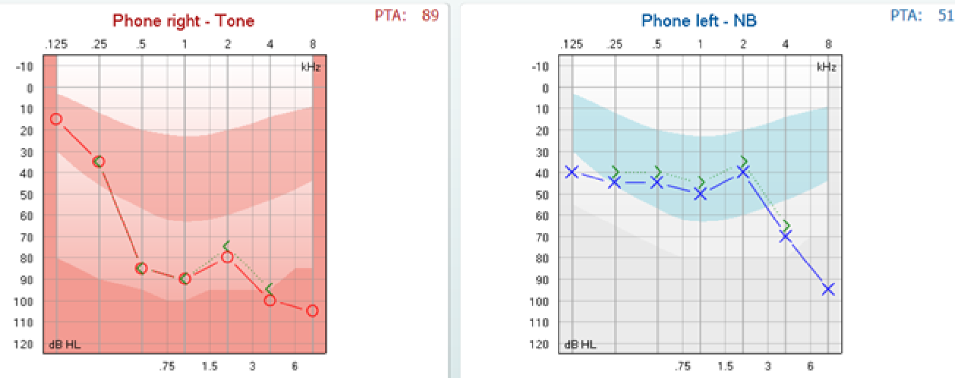
The physical examination of the patient yielded no relevant data, the ENT exam was within normal limits.

The vestibular examination pointed out to an important instability, the patient was unable to maintain orthostatic position or walk without support, no spontaneous nystagmus.

The cerebral IRM examination did not reveal any vascular or tumoral lesions. The neurologic examination did not discover any motor or sensorial deficit, no signs of localization.

The audiogram performed initially can be visualized in Figure 1. We diagnosed a profound sensoryneural hearing loss for the right ear and a medium sensory-neural hearing loss for the left ear.

Figure 1: Initial audiogram



The rheumatologic examination revealed no remarkable findings: no arthritis, no cutaneous lesions, and no ocular symptoms.

The blood hematological and biochemical parameters were modified showing a slight leukocytosis with a white blood count of 11000/mm^3, the ESR also slightly elevated 25 mm/hour and the CRP had the value of 5. The modifications were interpreted as a reaction to an acute dental infection the patient had at that moment.

All the immunologic tests we performed were in normal limits, IgA, IgG, IgM, ANA, antibodies anti beta 2 glycoprotein, antibodies antiphospholipid were tested and the values were normal. Antibodies Ig M and Ig G for Epstein Bar virus, Toxoplasma, HIV, herpes virus, cytomegalovirus were all negative.

The ophthalmologic examination did not find any modifications of the anterior ocular pole at that initial moment.

The computerized posturography we performed at admission showed a severe vestibular deficiency pattern (Figure 2).

The videonystagmography with caloric testing evidenced a total right areflexia and an extremely important left hyporeflexia (Figure 3).

We started a treatment with high dose corticotherapy (solu-medrol), antiemetic (osetron), vestibular suppressant (diazepam), vasoactive agent (pentoxyphilin), vitamin (B1 and B6), plasma expander(dextran 40).

During the treatment, the patient presented a fluctuating evolution. The hearing level fluctuated especially on the left ear with PTA between 30 and 60 and on the right ear with PTA between 60 to 90.

In Figure 4 it can be noticed the aspect of two audiograms we performed during the treatment in which we could observe the fluctuant hypoaccusis in both ears.

The dizziness also fluctuated with episodes of severe vertigo. In these episodes, the direction of the nystagmus varied. We recorded horizontal rotatory nystagmus beating to the left but also to the right (Figure 5) alternating with periods of lack of nystagmus.

Figure 3: Videonystagmography

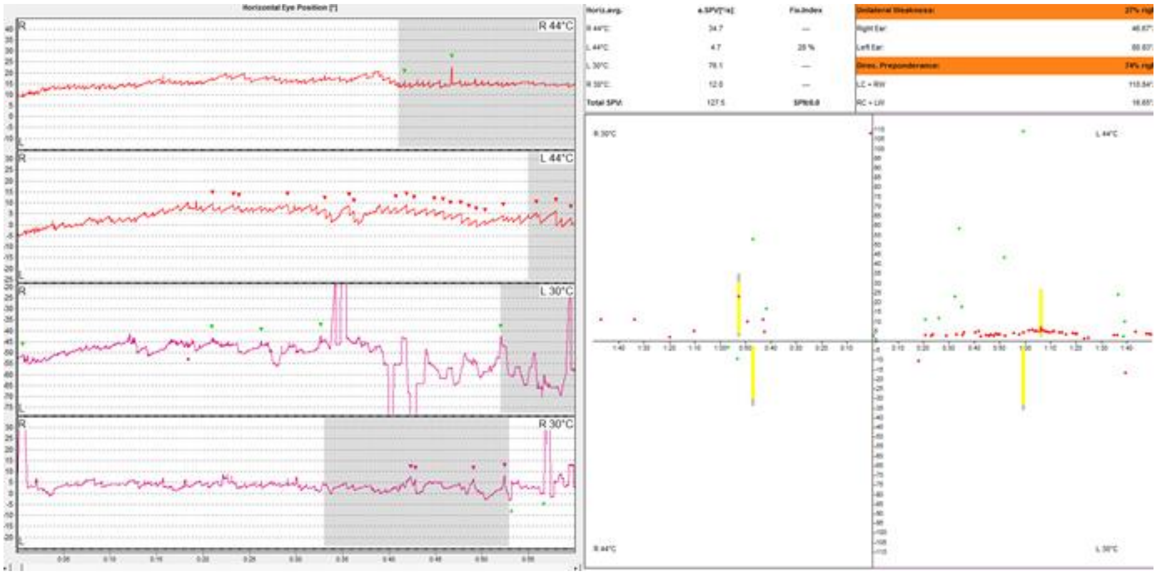

Figure 4: Audiograms during the treatment

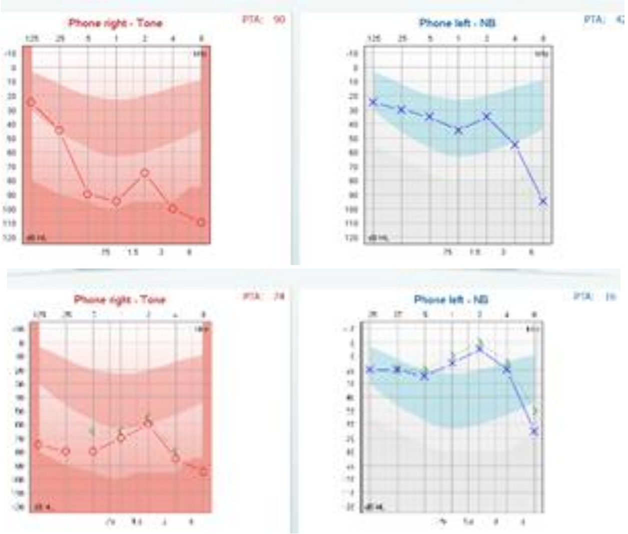

Figure 5: Horizontal rotatory nystagmus beating to the left but also to the right, alternating with periods of lack of nystagmus

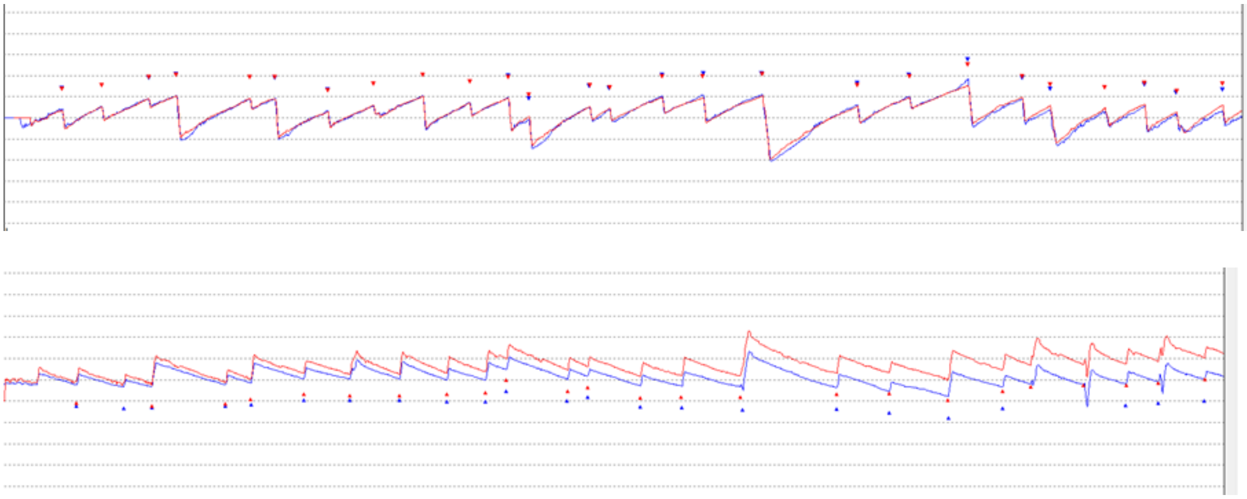
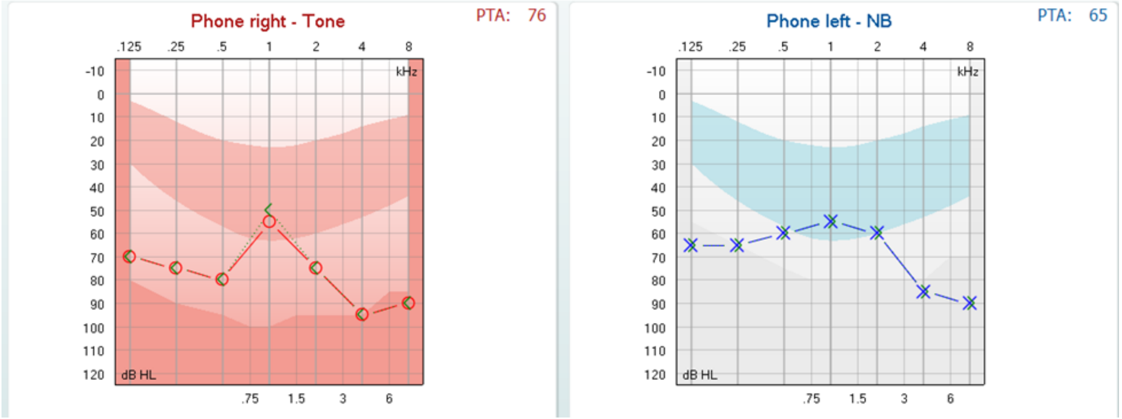


After 10 days of treatment in the hospital, the patient was discharged with an improvement of the hearing loss in the left ear, no vertigo and only a mild dizziness.

One month after this episode, the patient presented once again at the emergency department accusing intense vertigo, nausea, vomiting, tinnitus and aural fullness in the left ear. The audiogram evidenced a bilateral severe hearing loss (Figure 6).

Figure 6: Bilateral severe hearing loss



The rheumatologic examination did not reveal any modifications. The second day of hospitalization the patient suddenly presented eye pain with intense redness of the conjunctive. The ophthalmologic examination established the diagnosis of kerato-conjunctivitis (Figure 7).

In this moment, we were able to diagnose an atypical Cogan syndrome taking into account the association between the audio-vestibular symptoms with an inflammatory ocular disease.

We repeated the same treatment as in the first episode associating local eye topical corticosteroids and artificial tear solution with a major improvement of the hearing loss for the left ear PTA 10 (Figure 8).

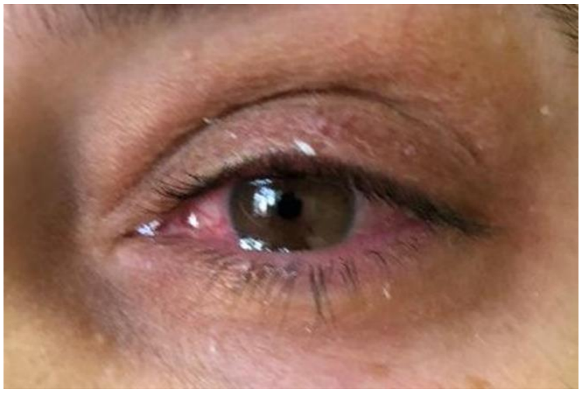
The patient was discharged with a prescription of prednisone in low dose for a period of three months.

One year later, in the follow up, we noticed that the hearing in the right ear did not improve at all but the instability improved a lot so the patient was able to continue with everyday life. In this year she did not have any attack, no audiovestibular or ocular symptoms.

DISCUSSION

Haynes et al described atypical Cogan syndrome for the first time in 1980. The typical Cogan syndrome was described as an association between Meniere–like audio-vestibulary symptoms and non-syphilitic interstitial keratitis with an interval between the onsets of the symptoms of less than two years.

Figure 7: Kerato-conjunctivitis



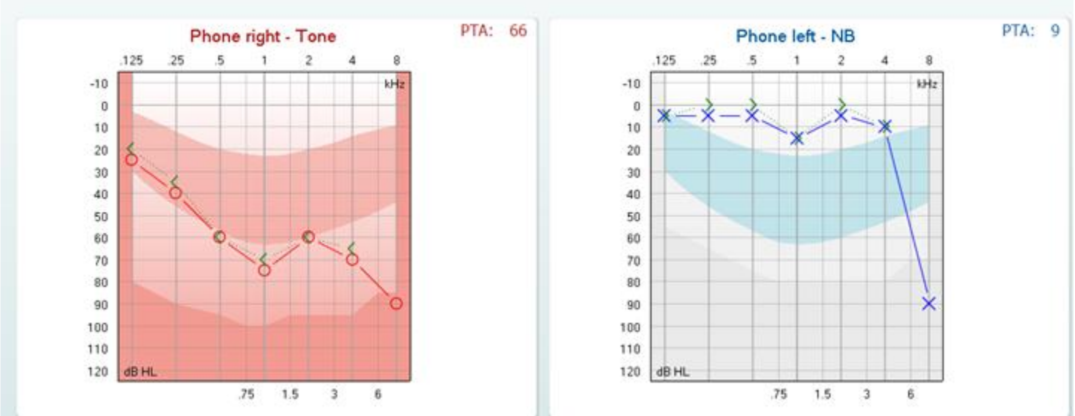
The atypical Cogan syndrome consists in an association of symptoms in which the disease criteria are grouped as follows:

- Inflammatory ocular manifestations with or without interstitial keratitis
- Typical ocular manifestations associated with audio-vestibular symptoms different from Meniere's
- A delay of more than 2 years between the onset of typical ocular and audio-vestibular manifestations.

The atypical Cogan syndrome with ocular manifestations other than interstitial keratitis tends to have a higher rate of systemic involvement with aortitis and has a worse prognosis. [3, 16]

It is the case of a 40-year-old woman with acute onset of intense audio-vestibulary symptoms with no remarkable medical history and no other general manifestations. At the first presentation the diagnosis of presumption was Meniere disease but there were characteristics of the evolution that did not entirely correspond. The disease was rapidly onset with bilateral and unequal involvement. The right ear had a profound hearing loss from the very beginning and practically did not respond to treatment. The left ear had a minor amelioration in the first episode and quite a good response in the second episode of the disease although the treatment was similar. During the admission we performed multiple audiograms evidencing the fact that the thresholds at both ears were in a continuous modification, not respecting the classical pattern of Meniere's. The videonystagmography with calorics showing bilateral vestibular lesion from the beginning of the disease, was also atypical for Meniere.

Figure 8: Major improvement of the hearing loss for the left ear



The onset and evolution of the disease made us believe that there is a autoimmune disorder of the inner ear but we did not have any disease criteria to classify. The laboratory tests were within normal limits, the minor leukocytosis and the slight elevated ESR were not noticeable. No other immunologic tests were modified or virus infections detected.

At the second episode of disease, the concomitance with the kerato-conjunctivitis was consistent with the diagnosis of atypical Cogan syndrome. We consider that this is the only disorder that can be taken into account for the diagnosis of this patient. Another remark is the fact that the patient is over the age of typical onset of the disease, but there are many reports of atypical Cogan with patients in the same age group. [17, 18]

The response to corticotherapy, was partial as the right ear did not recover, but the final result was considered satisfactory by the patient who could continue her daily activities.

CONCLUSION

Although Cogan syndrome is a rare disease, we must bear in mind that there is always a possibility of diagnosing it in the case of a patient with both vestibule-auditory symptoms and ocular manifestations.

Typical and atypical Cogan syndrome are diagnosed mainly based on clinical criteria as there are no laboratory tests able to evidentiate the disease.

The treatment consists mainly in corticotherapy. Immunosuppressants are an option in cases where corticotherapy is inefficient.

Patient-physician communication, an essential condition for an effective medical act

Carmen M. Voicu[1], Consuela M. Gheorghe[1]

An inconceivable reality for the medical world today is to consider the patient an active factor in his own healing process. Placement of the patient in the center of healthcare services aims at his loyalty, which means creating and maintaining correct and long-lasting relationships with him. In addition, in order to create such relationships with patients, both loyalty and stability, performance, and profitability strategies of the medical team must be thought on long-term.

Healthcare marketing situations differ, and medical units concerned with the essence of success must strive for a strategic alignment of relationships between all stakeholders (decision-makers, medical staff, patients, etc.) and the power of these relationships to improve their mutual value and even the relational context as a whole, turning patients into true brand promoters, thus enhancing marketing efforts [1].

The patient reaches to attitudes, judgements, and preferences about certain brands through a procedure of evaluating the features of these brands, developing a set of beliefs about the features that correspond to each brand [2].

Recognition of the strategic relationship that a patient desires is a medical marketing reality and involves greater commitment to accepting the challenge of creative thinking in often difficult situations, progressing through knowledge and understanding to mutual trust, converting emotions into balanced normality and the relationship thus created into an emotional-connected and loyal one for a certain period of time. This means concentrating efforts on patients, attention, and receptiveness to his wishes, but professionalism and rigor in such a way that his personal health expectations are not in vain. Moreover, it is very important to pay a close attention to communicating with him; it is even said that this type of communication is the broker of the relationship developed in a sensitive and dynamic environment like the healthcare field.

The complexity of providing healthcare services, on the one hand, and the wishes and expectations of patients, on the other hand, have as result special patient-physician communication valences and turn it into an essential condition. Permanent and effective communication with patients has become a condition of the existence of a qualitative medical act.

Given the continuous increase and diversification of health services, communication issues are becoming increasingly difficult and require much more laborious information efforts.

Due to the information explosion, patients tend to appreciate the quality of a product or service based on perceptions rather than on reality.

That is why efforts to optimize the technological and informational processes of communication between patients and medical staff, of exploring patients' behaviors regarding interpersonal communication in electronic environments in health services, of modeling negative emotions, of ways of transforming the healthcare infrastructure so that it offers an integrated insight of information through the optimized clinical and business processes, of welfare and health management, of patient-centered networks, of investigating the influence of virtual communities on the reputations of health organizations in Romania, has become a permanent necessity [3].

The relationship between the two sides, medical staff-patient, in the healthcare field, is much more complex, addressing social, psychological, and cultural aspects, which besides the base of the therapeutic level also implies a superior level of existential communication. The latter is found in medical communication because the medical act interferes with the destiny of the patient, linked in turn with elements of uncertainty and individual instability [4].

Interpersonal communication was the first spiritual instrument of the human being in the process of socializing, and is defined as the communication that occurs between two people in the context of their relationship and which, as it evolves, helps them negotiate and define the relationship [5].

Communication within the health organization takes place in a complex environment, where continuously modifying favorable and unfavorable factors coexist. Communication can take many forms and can be seen in different situations, but the most important of these is undoubtedly between patient and physician, which provide much of the data needed to establish the diagnosis and therapeutic attitude.

Interpersonal communication is formed by the combination of verbal forms (oral and written), nonverbal forms (gestures, mimics, posture, movement, aspect) and paraverbal forms (by voice attributes accompanying the word, such as intonation, rhythm, verbal flow), but, considering the importance of the information content of patient-physician communication (the diagnosis and treatment process), in the medical system, the emphasis is more on verbal communication. Non-verbal and paraverbal forms are important from the point of view of their emotional effect and the formation of sympathy.

In the health system, the relationship between the two sides, the medical staff-patient, is much more complex, involving a higher-level therapeutic type of existential communication. This type of communication [4] is involved in medical communication, because the medical act interferes with the destiny and evolution of the patient, being in turn linked to elements of uncertainty and individual instability.

On the other hand, the position of the two entities, namely the medical staff-patient, is different and unequal [6]. This relationship is established between members of two distinct social groups in terms of their prestige, power, and orientations. Thus, the physician has an extremely high status, given the level of information held and the specialized guidance through which he exercises his full authority.

The social role of the patient demonstrates his vulnerability, being forced to seek support whenever he needs. Thus, the patient is the most disadvantaged person, being influenced by physical and mental suffering, feeling the disease as a source of uncertainty and insecurity, while the physician is regarded as a person with multiple qualities, full of energy and sometimes with magical powers.

Gaining a high communicative competency needed by the specialist to create a real therapeutic alliance requires not only solid medical knowledge to diagnose and treat the disease but also the ability to obtain as much information as possible from the patient and interpersonal skills to respond to feelings and patient concerns and the ability to create and maintain the therapeutic relationship as a concrete offer of information and medical education [7].

Health communication is “the study and use of communication strategies to inform and influence the choices people make regarding their health”, and health information technology includes “digital instruments and services used to enhance self-care of patients, assisting patient-provider communication, informing about health behaviors, preventing health complications and promoting equity in health” [8].

A major concern of health services and primarily of hospitals has become communicating with patients, the quality of information provided to patients by physicians and the rest of the medical team. An essential component is the transmission of information, which has become increasingly important in medical deontology. This development is primarily driven by wishes of patients, more trained in health issues, and more cautious about the quality of the explanations they are given.

In the hospital environment, where the patient is subject to the attention of medical teams, the coherence of “what is said and what is not” becomes a permanent goal for patients and their relatives. Because, beyond anything “...there is an informational asymmetry between the physician and the patient: when they find themselves in the hospital (...), they feel ill, they do not feel what is going on with them, they do not know the possibilities of medical science, so they empower the physician with the freedom of choice” [9]. A good professional behavior is to state exactly how we are feeling and to write what we are saying. However, each physician is the supreme judge of how he or she does and can enrich his or her oral information by using information charts and, if considered necessary, by other documents or video support.

In healthcare services, access to online information has made patients more aware of their needs and desires so the result has materialized in a rigorous selection of service providers.

Therefore, healthcare managers and providers need to understand the stages a potential patient is going through in an online buying process or when expressing an intention to buy an online health product or service.

The winners will be those who build trust from the patient's perspective, with three progressive complex components in the relationship between the brand and him: credibility, care, and congruence. Certainly, what is very important is the amount of money spent by the patient for the recovery of health.

Nowadays, in health systems, the widened marketing mix enjoys considerable attention. It provides a simple organizational mechanism to understand the problems arising from the concerns of medical service providers. The widened mix has also developed as a partial solution to some of the most important problems faced by managers in terms of quality control of healthcare services provided and the relationship with patients in the process of providing these services. The widened mix explicitly recognizes the role of the staff and patients in the service delivery process, highlighting the role of marketing played by both sides.

The inclusion of Physical Evidence, Participants, and Process as distinct (contextual) elements underlines their importance and impact on marketing of health services. In addition, the key objectives are to increase patient satisfaction, quality of medical services offered and long-term patient gaining, which means that the widened marketing mix management is directly related to these objectives.

Due to the immaterial nature of healthcare service and the fact that, usually, they cannot be checked beforehand, patients are looking for tangible evidence of what they are about to experience in a particular immediate confrontation with the medical service. Even if a patient has a high experience with such a healthcare provider, variations, and contextual elements will affect patient's expectations related to the immediate confrontation with a medical service.

Elements of "Physical Evidence", such as noise level, smell, temperature, time, comfort, and even nutrition, will influence the perceptions of confronting with the healthcare service requested. Similarly, the attitudes and behavior of healthcare participants will influence the perceptions of current performance. Contextual elements can also influence satisfaction in the confrontation with the medical service, through their effects on attributions (of causes) for invalidation. Theory of attribution asserts that when results are not in line with expectations, people tend to look for reasons. The importance they give to "why", will influence the final evaluation of the outcome.

The communication process is very important within the medical unit; it is a process that affects the quality of the other processes. Through the positive impact on communication within the medical unit, the style oriented towards maintaining socio-emotional aspects and the leadership style oriented towards relationships is beneficial to the processes within the medical unit and to the emergence of positive socio-emotional states. This leadership style is associated with the existence of high quality communication relationships, which leads to the improvement of the quality of the other processes [10].

In the new context of health, development processes will need to focus not only on solving current problems, but also on anticipating future problems, not just on certain types of processes, but as many as possible, not just on technical resources, but more on human ones. Organizational-managerial excellence seeks not just the adaptation to circumstances, but also the becoming and the power to create the circumstances [11].

The depth of the process of change in health, its size, and its dynamics depend not only on the political will and on the subjective aspirations, but also on the existence and sufficiency of the necessary objective conditions, the managerial ones being the first.

In the context of today's healthcare problems, the special role of the manager is imposed by the need to create a general capacity for innovation, flexibility, stability, and ensuring success even in extreme situations. In this context, the theoretical but especially the methodological approach of the marketing of the medical system has special practical valences, requiring a change in the mental attitude of health managers towards an innovative strategic hospital marketing oriented towards and for the benefit of patients [12].

The tree we throw stones at

Mihail Mihailide

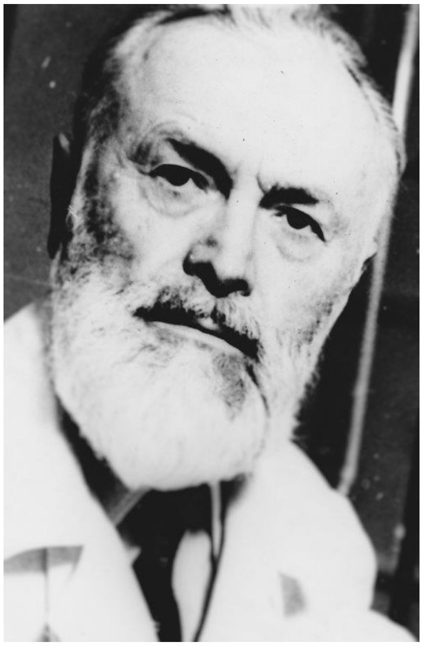
I stop to catch my breath on the crest of a hill in Predeluţ.

It's late autumn with a blue-diamond sky. Nevertheless, there is fresh snow fallen on the rugged tops of the mountains and on the hedges of dark fir trees at the foot of the Bucegi mountains – looking as if they were mounted lancers. The snow is glistening.

I feel the tall grass, dried by the season, under my feet. On the twisted and black branches of the old apple trees, red fruit swing in the scented wind. Around the roots of the some apple trees – there are spots of royal purple perennial irises. Although poisonous flowers, I can't resist their calling beauty and I lift a few threads.

Back on track, I turn my bicycle towards Bran, I descend by the Castel, pass by Vama Medievală, and ride along Turcu River to the place where it sweeps in Șimon stream. Then I turn left and head towards the Brandeberg guesthouse. Here I securely park my "Pegas". My destination is not the hotel but the building across the street, Parascheva Holy Church, on 340, Iancu Gonţea Street, whose frescoes were painted about three centuries ago by Nicolae Zugravu from Turcheş – Săcele. It is believed that he also put his talent at work at the Three Holy Hierarchs Monastery in Iași.

My objective as a traveller is not the church but the "cultural and medico-historical heritage" provided by the resting places around this holy edifice. Many important Romanian intellectuals – several of them physicians – were born in the village of Bran, today a tourist attraction, but also in the nearby villages; many sleep their eternal sleep in the cemetery of Şimon village, under crosses with their names engraved on them. I intend to leave the bunch of irises on Iancu Gonţea's grave… The surrounding mountains and the forests that reached the yard of my house when I was a child were like the lords of the land for me... It is at Şimon that I built a vault in order to make sure that I would not sleep my eternal sleep anywhere else. "Today, a commemorative plaque and the name of a street in Bran remind us of this son of the region", noted Emil Stoian, the brave chronicler of this beautiful mountain village, to whom the inhabitants owe a major contribution for preserving the image of those who really meant something for the Romanian people. Such people are numerous, in Bran: historians, philologists, lawyers, physicians, actors, officers, priests, professors and academicians; participants in the Great Union of 1918; heroes of the two World Wars. I have met some of the physicians...



Found at the location, I feel disappointed: where is the tomb? I am told to go two kilometers uphill on the right side of the road. This time I decide to walk. Indeed, after passing the Primary School, on the yellowish wall of which a thin marble plaque reminds that the scholar attended his first classes "here", I pass by the house and the yard where he was born and spent his childhood, its gate always locked, and arrive at the church dedicated to St. Nicholas, standing a few meters retreated from the main street. Here, behind the building is a small cemetery. At its end, close to the hill, I finally find the vault: "Fam. Prof. Dr. Doc. Iancu Gonţea" with two rows of vertical crypts! It looks rather like a bunker. In the crypt by the side of the teacher lies his wife, Dr. Lucia L. Gonţea (1907-1998, born Popescu) buried 22 years after the professor.

From an oval photograph, embedded in the austere concrete wall, the professor gives me a harsh look. Where should I put the irises brought as a modest homage? It's difficult to find your way between the graves...

I have synthesized ergo-biographical data regarding Prof. Iancu Gonţea in a book [2], using sources coming mainly from the archives of the medical-historical documentation library of the National Public Health Institute of Bucharest, an institution whose enrichment with new information (manuscripts, photos, video tapes, books, magazines, etc.) and modern digitization was stopped for various reasons... Iancu Gonţea was one of my professors in my fourth year at the Bucharest Faculty of General Medicine. Decades have gone by. Before proceeding to "serious things", I ask the reader's permission to reproduce a few paragraphs, surely forgotten by the reader, perhaps funny, from the notes about the professor of the Food Hygiene Department, who was born in Şimon and returned there at the end of his life.

PROFESOR DOCTOR DOCENT
IANCU GONȚEA
n.10.02.1907-d.15.03.1976

"We were two groups of fourth-year students of General Medicine, huddled in front of the laboratories of the Institute of Hygiene in Bucharest, where we were to take an oral exam in Food Hygiene. The professor – an unforgettable person... tall, slim, with penetrating eyes and a Hemingway-style beard, wearing an impeccable white gown – was sitting at the teacher's desk, on a podium, with the assistant group on his right, and us, the wretched students (oh, how we cried out for mercy knowing his exigency!), one step down, in front of the examiners, at a tiled table full of Erlenmeyer balloons, pipettes, tripods, test tubes and dropping bottles. Usually, this type of final exam was the responsibility of the associate professors. It was only exceptionally that the professor would waste his time with us. Well, there we were, living... the exception! Each of us picked from a jar the ticket with the subjects written on it, thought of them for a few minutes and answered the three questions, in the order in which they were typed.

After ending our monologues (rather scanty, more often than not), followed a dialogue with the professor, Iancu Gonţea himself. At the end, he wrote down the grade that each of us deserved in our grade-books and we tiptoed out of the lab. In the hall, we were approached by our classmates who, browsing through their notebooks, were trying to learn everything they hadn't learnt until then, before entering the lab room „to have their heads cut off".

– What subject did you pick? Does he also ask questions from «the practical experiments»? Is he harsh, is he kind? What grade did you get? Many of the questions were difficult to answer promptly... At a certain moment, one of the best students of our class came out of the lab, almost bursting into tears, obviously confused.

– What happened? What subject did you get?

– The third question, she explained us, as she started to feel better, was about the trophic content of the main foods. I explained how many proteins, lipids, fats and calories can be found in cow's milk, eggs, fish, chicken and I don't know what else I mentioned... I couldn't realize whether he was satisfied or whether I had gotten it all wrong. I finished what I had to say, but then he asked me additional questions, looking at me over his glasses:

– «What about ordinary vegetables, which of them have a higher vitamin content?» I gave the wrong answers, I stammered and then I said: carrots, spinach, tomatoes... Whatever!

– «What a-bout-par-sley?» he asked. I was as quiet as a fish. Total silence. He gave me the right answer and explained why his question was so important. Then he added:

– «Veronica, Veronica! You didn't really like Food Hygiene…» And then I saw him write 5 (five) in my grade-book and sign it. «You should come in the autumn to get a higher grade! he said, probably thinking that I would otherwise lose my scholarship…

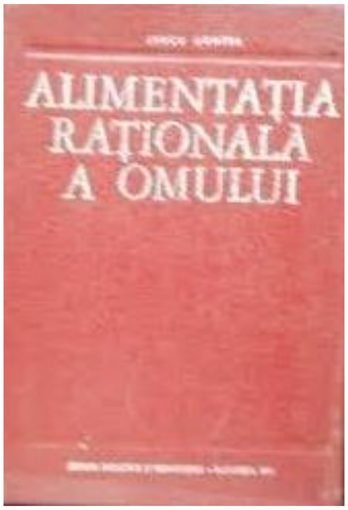
The professor's question was not tricky, he had indeed told us in his lectures that parsley contains more vitamin C than lemon, orange or cabbage and, in addition to that, it also contains vitamins A, B1, B2, B6, K and E, as well as all the minerals useful to the body. Parsley is an antioxidant, antiallergic, antitumoral, which stimulates the gallbladder secretion, maintains elasticity of the vessels, and I can no longer remember now, more than half a century later, what other wonders we owe to this herb, commonly used for flavoring and adorning dishes!

Veronica had only remembered what the professor's assistant had told us at a seminar, smiling, about the qualities of this ancient vegetable: «It also ensures the good functioning of the genitals and even has a powerful aphrodisiac effect! »"[3]

Writing about himself in a curriculum vitae requested by the Academy of Medical Sciences (AMS), whose member he became, professor Iancu Gonţea believed that he had set a "new trend in the science he practiced, which was seen not only as food hygiene, studied separately from the man (in a narrow technical-sanitary concept), but as the science of biomedical, psycho-social, and economic relations between man and food"[4]. He has the merit of having contributed to determining the nutritional requirements in relation to one's occupational and environmental conditions, «for the first time demonstrating that physical activity increases protein and calcium needs, as well as vitamin C consumption, [and that] exposure to chemical noxae heightens the metabolism of thioamide acids and of ascorbic acid, increasing the needs of the body.»

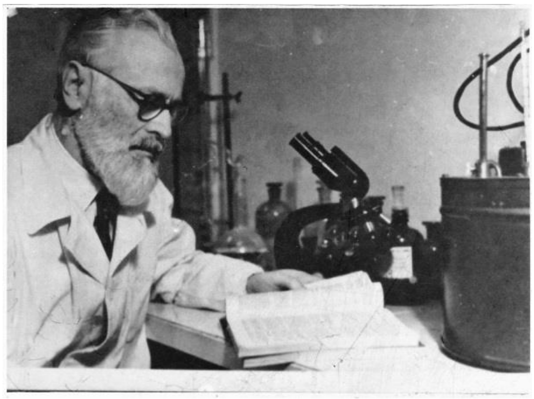
In the same CV requested by the Academy of Medical Sciences, the professor listed the procedures he had devised for the biochemical control of vitamin nutrition status, as well as the methodology for studying the biological value of food, both highly appreciated by international scientific bodies.

The professor was to be awarded an important international prize (Maurel) as well as the silver medal in food science for his contribution regarding natural anti-nutritional substances in food and animal feed. I. Gonţea also demonstrated that no food is complete and set up an original classification of foods (by groups), embraced by experts of his time, in keeping with the benefits and the deficiencies of various food categories."[5]



Given their originality and practical value, based on rigorous laboratory and field research, many of his writings have been translated into widely-circulated foreign languages. They cover the fields of effort physiology, pathophysiology, and medical clinic, but most of them include research on human nutritional needs under different physiological, occupational and environmental conditions: "Food Control" (1956), "Food Ration" (1956), "Rational Nutrition of Women during Maternity and Its Importance for Mother and Child Health" (1958) can be considered as major landmarks in medical literature, at least in the Romanian one. The last of the books mentioned were updated by the author, translated into German, and published by the prestigious publishing house

Gustav Fischer of Jena in 1965. Having received excellent reviews, this monograph was requested, from the German publishing house, by Dai-lichi Co. Ltd. Publishing House in Tokyo and became the first book by a Romanian scientist published in Japan, in 1974.



In 1963, the Medical Publishing House (Bucharest) released "The Bases of Nutrition". Three years later, another book was published: "Natural Anti-Nutritional Substances in Food and Animal Feed" (in association with Paraschiva Şuţescu, Ph.D.), subsequently translated into French and published by Vigot Frères Publishing House, in association with prof. Raymond Ferrando PhD (Paris, 1967), as well as into English, and published by Karger Publishers in Basel (Switzerland) [6] as well as in New York (1968). The Academy of the Socialist Republic of Romania awarded professor Gonţea the "Victor Babeş" prize for this book. Among the books that were published, almost every year, two titles still stand out, several decades later:" A Genetic Leap in the Nutritional Value of Corn – the Past and Present of this Cereal" (Ceres Publishing House) and "Alcoholism" (Medical Publishing House, 1976), an insight from the point of view of preventive medicine into the use and over consumption of alcoholic drinks – "considered to be a serious problem on a national level".

Professor Iancu Gonţea won high recognition in the scientific events he was invited to — international congresses and symposiums (Dresden, Moscow, where he accompanied the Romanian delegation as an expert in nutritional issues at C.A.E.R. meeting, 1969), at New Castle ("Women's Nutrition during the Reproductive Cycle", 1971), Mexico (where he presented a paper titled "Nutrition and Anti-Infectious Defense in Humans"), Austria ("The Effects of Sugar Abuse") etc. He received national and international awards and diplomas.

Under a Decree of the State Council of the Socialist Republic of Romania (153/1971), the professor was awarded the "Sanitary Merit", alongside other scientists rewarded "for the contribution to the Party's policy in the field of public health in our country". The chairman of the Council at the time was N. Ceauşescu, while the minister of health – Prof. Dr. Dan Enăchescu.

The fact that the romanian scholar did not also become a member of the Academy is rather amazing, since, forgive my insolence, many others were comfortably sitting in the "immortals"' seats of the Academy of the Socialist Republic for (scientific!) achievements, which, compared to his own, were a lot less significant...

*

Who would have thought that professor Iancu I. Gonţea – a former military physician (promoted major in 1948), hence a person whose past and family had been under the close scrutiny of the army's newly set-up personnel department and who had a "healthy" origin (being the son of a shepherd, born in the village of Şimon, on February 10, 1907), and therefore, seeming to be imbued with socialist "principles" and "ethics" – was to be placed under surveillance by the Securitate (being the subject of two files, "I. 498910")? [7]

He maintained correspondence with scientists from all over the world; often travelled to Western countries but also to the Soviet Union; he attended medical conferences; worked in the field of food hygiene, this having a great social impact. He represented the Socialist Republic of Romania in the World Health Organization. All this supposed that his loyalty to the "party and to the socialist homeland" were to be continuously tested by the "state bodies"...

The "vigilance" of the Securitate also translated into an internal decision issued on November 18, 1969, regarding the preservation of his "informative" file in the Operational Fund, under no. I. 715753, coming from the 3rd Directorate of the feared institution…

What was pursued Iancu Ion Gonţea accused of?

That "he was a member of the Iron Guard, working in the Sanitary Department of its Documentary Studies Center." That, "he was a major in the bourgeois army" (a member of the contingent of officers who took the military oath before the King). Later on that "he maintained correspondence with people from abroad, such as Prof. R. Ferrando (France) and foreign publishing houses." In an informative ("strictly secret") note obtained by major I. Ion, at agent "Gabriel" home and dated April 17, 1967, he declared that he met the person under surveillance during his studies at the Andrei Şaguna High School (1924-1927) and added that Iancu Gonţea (I.G.) "was a very good student, who graduated at the top of his class".

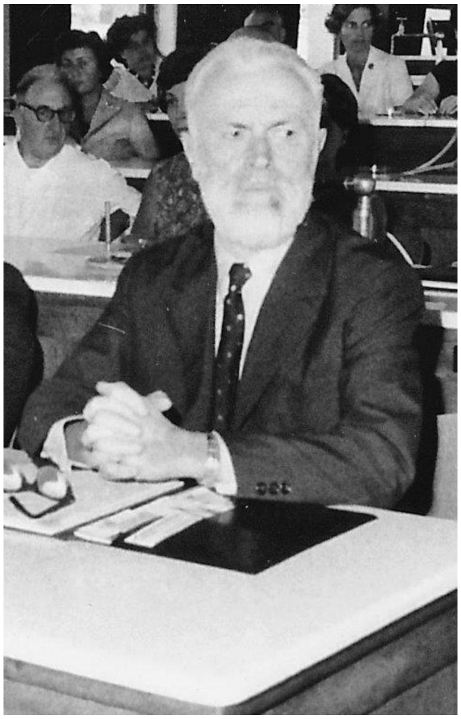
The note provided biographical data, generally consistent with that provided by Gonţea in his résumés. I.G. seems to been the son of poor peasants from Bran; he was not perform any legionary activities, although his uncle, a history teacher, dr. [Ioan] Moşoiu, "who was also the manager of the high school (the Andrei Șaguna Romanian Orthodox high school in Braşov) was known for his involvement in the legionary activity (he was the Commander of one of its local branches). After graduating from high school, I.G. joined the Medico-Military Institute (Bucharest) and "Gabriel" went to Prague. After 1948, they met again in Bucharest, on a daily basis, since I.G. taught at the Institute of Hygiene.

Despite being rather ill (suffering from diabetes), I.G. was very active, becoming a professor and the head of the Food Hygiene Department (Bucharest Institute of Hygiene). He was highly valued as a specialist, "Gabriel" convincingly using the communist jargon of the time: he "combines theory with practice and links laboratory research with practical activities, such as supervising in bakeries, canteens, etc." He had a vast journalistic activity, "Gabriel" citing in I.G.'s defense his contributions to Scânteia and Economic Life newspapers, ahead of the papers published in specialized magazines…

Next came a significant detail: although generally he did not have an active social life, I.G. celebrated his 60th birthday by organizing a "comradely lunch at the Faculty of Military Medicine". Among the guests featured professor [Nicolae] Nestorescu, a microbiologist and immunologist (who also was a former military physician) and lecturer Coman Petrescu, PhD (a pediatrician dealing with rational child nutrition). In "Gabriel"'s opinion, allegations that I.G. had been involved in the legionary movement activities as a student were simply "unfounded rumors."

However, in his Note, major I. Ion seemed keen to show his superiors how cautious he was: "Since I.G. is known by the Third Department (of the Securitate) as a former member of the Iron Guard, the agent will have to inform us of any data backing this assumption. In addition to that, the correspondence with foreigners will be kept under observation." Next came a list of names – French and German researchers and professors from (Paris) and (Heidelberg).

Here is what agent "Titi", who "kept him under observation during his teaching activities", wrote: "Always punctual, having a commanding attitude, he teaches the students notions of food hygiene during his two-hour lecture. During his lectures he seems to speak with passion, having a dignified attitude. From talking to other students, the source found out that professor Gonţea is very demanding during exams, asking the students to reproduce all the details, or better said the whole lecture, word by word. He does not hesitate to turn students out over the slightest mistake. His behavior gives the impression of a modest man, deeply involved in his profession."



Elly – a professional informer

In Iancu Ion Gonţea's file, there is a note received by captainV. Ovidiu, on April 19, 1957, from agent "Elly", reeking of antipathy towards I.G., a text in which one can hardly tell the truth from "pure" lies. It is difficult, if not downright impossible, to check these allegations because the informer, hiding under the pseudonym given her by the Securitate, seems to be a professional of delation, citing people (giving their full names and the position held in the Institute) who could allegedly back her allegations, but who today, 60 years later, are most certainly dead...

"I inform you", wrote Elly, "that Dr. I.G., associate professor of nutrition at the Faculty of Medicine, living at 244, Dorobanti Street, phone 7.66.29, claims to be «untouchable» because he is backed by Acad. Ștefan Milcu and Acad. N. Lupu, who are «indebted» to him.

I.G. is the author of numerous fake public documents and characterizations (within the IMF – Institute of Medicine and Pharmacy), helped by former head of the personnel department At.). All these facts are known by the management. Dr. I. Per. from the Hygiene Institute, Laboratory of Food Chemistry, 1, Leonte Street, can provide references in this respect."

After this "introduction," "Elly" wrote that she knew I.G. since November 1954. "I know that he was a legionary, working in the cabinet of another Iron Guard physician, Dr. Ru, within the Legionary Ethics Committee – at the time, the steering committee of the Faculty of Medicine (?). At that time he worked wearing a green, Iron Guard shirt; at Iron Guard rallies he carried banners reading Nu merus nullus (sic!) and Nu merus claus (sic!). prof.dr. I.I.N., manager of the Institute of Physiology of the R.P.R. Academy, phone 4.20.59 (home) and Dr. Eug. D.), phone 7.31.16 (home) can give references about his activity at the time. Among the acts of hooliganism, I can mention the ones I heard about from Dr. Eug. D., namely that Assoc. Prof. Dr. I.G., under the legionary régime, tried to devastate the Cantacuzino Institute, kicking the doors when he entered the rooms, destroying laboratory equipment, etc. In the Military Sanitary Institute where he worked for some time, the whole institute knew him as a "passionate Iron Guard member" (Dr. Iac., Assistant at the physiology department, tel. 3.27. 90 ,home, can give references about this). In the bourgeois army, he was highly regarded because of the wealth he still holds, to a great extent:

- Mansion in Călimanesti
- Estate and mansion in Bran
- Houses in Bucharest
- Car etc.

Later on, Assoc. Prof. I.G. proved to be a hostile element, pleading in favor of Antonescu's criminal actions against the USSR. References: Dr. Eug. D. and Dr. P.

Thus, Assoc. Prof. Gonţea maintained ties with his former collaborators from the Legionary Nest, Assoc. Prof. Pr. Gh., from the Physiology Department, with Tudor G., also from the Physiology Department, with G. Maria from the same department, about whom I will tell you in detail further down. Assoc. Prof. I.G. has remained the same reactionary person, nurturing sympathy for the Iron Guard, and still indulging in hooliganism. Here are some facts:

1) He encourages the personnel not to apply for higher positions since exams are "based on the Russian model and have a temporary character". References can be given by C. Adrian, assistant at the Physics Faculty, phone 2. 68.09

2) Assoc .prof. I.G. sent two articles for publication to the Institute of Physiology of the Academy of the R.P.R. (People's Republic of Romania), registered with no. 36 / 6.III.1957 of the Nutrition Department:

- The bibliography of the first article includes 13 works, none of them Soviet.

- The bibliography of the second article includes ten works, all of them English and American.

- This amounts to hostile behavior towards Soviet science, and within the department, which contrary to the ideological orientation of the scientific research in the R.P.R.

3) He considers himself a "great patriot and a great Romanian". Under this mask, Assoc. Prof. I.G. hides his ferocious anti-semitism and hatred against elements dedicated to the working class. References: 1. Gabriela from Caritas, phone 2.90.40 who was an assistant at the Department of Nutrition, Dr. D. Eugen, phone 7.31.16; M. Maria. St. Constintin Street, No… Petre P. from the Cotroceni Hygiene Institute.

4) Assoc. Prof. Gonţea Iancu (hereafter names were blacked out by the CNSAS) – nurse G. Maria swore to me, in the autumn of 1955, on the health of her child, that, as head of the Nutrition Department, he had given her extra paid hours, the equivalent of a part-time job, [but] from the date of January 1, 1955 to September 1, 1955, he obliged her to give him 1/2 of her part-time wage. G. Maria told me this out of despair because (redacted by the CNSAS) his fabulous wealth helped him back the interests of the Iron Guard. [And] after she gave him this money, "which he literally grabbed from her and which were part of her due", as a reward, assoc.prof. Gonţea gave her the sack. The reason was another subordinate, dr. Şuţescu Paraschiva (anonymized words by the CNSAS) who [becoming a favorite] continued to work with I.G. G.Maria told me all this on the way between Ardealul Avenue and Plevnei Street, as she was going towards Progresului to the Rectorate of the Institute of Medicine and Pharmacy.

5) At the Nutrition Department, Assoc. Prof. Gonţea sells overpriced wool and veal meat from his estate in Bran to the staff, whom he obliges to buy, threatening to treat them badly if they don't. Assist. A. C. can give references, phone 3.11.10.

6) (Anonymised paragraph by the CNSAS) G. Maria was a notorious Iron Guard member, the daughter of the richest merchant in Constanța who lived in the countryside in Bulgaria until 1956, when she brought him back to Bucharest for good since "rich people are no longer oppressed as they used to be", according to her own words. G. Maria worked with the Legionnaires, being... (redacted). Thus she helped them set up camps in the V. Roaită resort and her father helped by providing food and transportation.

7) As far as his behavior towards students is concerned, I can mention that several of them have lodged complaints about his demagogic manifestations with the Dean’s Office of the

Faculty of Medicine, but to no avail. References can be given by student P. Aurel from the sixth year. His attitude towards the young employees of the Institute of Medicine and Pharmacy has remained fierily reactionary and he is doing his best to exclude those who had worked in ministries representing our régime. I am attaching the original statements by Prof. N., whom Assoc. Prof. Gonţea Iancu told that he would do his best so that Dr. Maria Mih. and her husband, C. Adrian, who had worked at the MAI [Ministry of Internal Affairs] would be sacked. C. Adrian was summoned to the C.C. of the P.M.R. for a mission, which Gonţea branded as a dangerous element for the reactionary clique he is a member of. (I should mention that the summons took place a few months after the appointment of assistant C. within the Medicine Faculty).

8) About Assoc. Prof. Gonţea Iancu's son, whose name is Gonţea Liviu, a fourth-year student at the Faculty of Medicine, I know that he was under investigation by the Ministry of Internal Affairs over hooliganism when he was a high-school student. I mention that Gonţea Iancu was connected to Lupaş Tudor, who provided him with articles translated from Hungarian, which had been broadcasted on the radio, which Gonţea Liviu handed to the students in his group. In a conversation with Tudor Geor., Lupas's uncle, who worked in the physiology laboratory, told me that «the guilty people are free while his nephew is in prison.»

When I asked him if Gonţea's son had been involved, he did not give a straight answer, but made me understand that he had."

(signed) Elly

We find ourselves in 1957, a few months after the Hungarian revolution (called "counter-revolution" by the Communists), when the vigilance and coercive measures of the Securitate got a new "boost", stimulating the activity of informants. Moreover, on October 27, 1956, in university cities, students were out in the streets demanding an improvement in living conditions, the removal of the Russian language from the educational curricula, and the liberalization of social life, demands which were followed by reprisals and arrests. Students and professors thus becoming a target of the newly established Ministry of State Security, an institution distinct from the Ministry of Internal Affairs, at the time led by Alexandru Draghici.

A year later, in June, a plenary session of the C.C. took place, announcing a return to the struggle against bourgeois ideology, criticism of intellectuals accused of snobbery, cosmopolitanism, apoliticism, negativity etc. Thus, the departure of the Soviet troops who had been stationed on Romanian territory for 14 years, did not seem to be auspicious to acts of dissent, especially from those who had had certain political views in the past, even if they had let themselves be carried away; on the contrary, it meant increased vigilance8.

Elly´s denunciations were obviously not based on "proletarian intransigence" or "ethical" reasons, but rather on personal, vindictive motives, which, after so many years, cannot be properly weighed. It is possible, however, that the "witnesses" mentioned by the informer may have considered themselves, for various reasons, harmed by the teacher (possibly by the exigencies that he imposed) or "stopped" in their desire for rapid ascension in the professional field or on the social ladder. In that period, the "weapon" at hand chosen by an informant in ensuring his success was invoking an alleged Iron Guard activity, or at least sympathy, on the part of the "target".

One of the graduates of the Faculty of Cluj (whose name was blacked out), was "promoted", as early as his student years, to a party activist, to the "Central Committee structure”! Starting in 1949, he held important positions in the state hierarchy: adviser to the minister of Health, then Sanitary General Inspector. He became pro-rector of the Institute of Medicine and Pharmacy in Bucharest (IMF) then, based on this rapid ascension and, of course, "being a valuable person", was named associate professor. (This rapid fast-lane promotion took barely six years).Since 1955 he engaged in research as head of department at the Hygiene and Public Health Institute in Bucharest. How could "Elly” not cite his name and indicate him as a credible witness in order to assess professor Gonţea's activity and behavior?

And what about another rival, born in 1884? The latter hoped that, thanks to the protection of his administrative superiors and by "revealing" I.G.'s alleged "Legionnary activity" and backing Elly's allegations, he could indefinitely extend his teaching term, in no matter what department, if Gonţea could be forced to give up the position he held «based on merit».

Nevertheless, we should mention that Elly´s detailed statements found in this file were not backed by any "notes" or testimonies given by the witnesses she cited.

After August 23, 1944, the issue of the legionnaires had become a major concern for the new power. In 1945, former legionnaire's members who were deemed as dangerous were arrested and sent to labour camps. Others were to be determined to become – and truly became – collaborators of the Communist Party, following Ana Pauker's intervention. On December 10, 1945, the Ministry of Internal Affairs issued an order "legalizing" some of the former Iron Guard members, who no longer posed a threat to the State and who had offered their services to the new régime. It was a bluff: the trio made up of Ana Pauker, Teohari Georgescu (minister of Internal Affairs) and KGB general Nicolski were later accused of having facilitated the infiltration of former Iron Guard members into the Communist Party. As a consequence, the three former Communist dignitaries were ousted.

At that time, however, the Legionnary Movement ghost had reappeared and informant "Elly" seized this opportunity to accuse Iancu Gonţea. It is true that many intellectuals, particularly younger ones, had sympathized with the Legionnary Movement in the 1930s, even though they later disavowed this affinity (see the notorious cases of Mircea Eliade, Eugen Ionesco, Emil Cioran.) Many intellectuals from the area of Braşov – Bran (eg, the great philologist Sextil Puşcariu), shared rightist, or even Iron Guard sympathies, an ideological confusion which they later regretted; among them there were also many physicians who had acquired some notoriety in their profession.

**

I once asked an older friend: why is there so much hatred towards a man who, through his knowledge and hard work, dedicated his life to medicine for the public welfare?

– "The he lazy man will throw stones only at the tree full of fruit, so that he can collect the fallen fruit effortlessly", my friend replied. "And then, we know from the Gospel that 'no good tree will bear bad fruit, nor will a bad tree bear good fruit.'"

ADMINISTRATIVE ISSUES

Guidelines for authors

Thank you for your interest in *Romanian Journal of Military Medicine.* Please read the complete Author Guidelines carefully prior to submission, including the section on copyright.

To ensure fast peer review and publication, manuscripts that do not adhere to the following instructions will be returned to the corresponding author for technical revision before undergoing peer review.

Note that submission implies that the content has not been published or submitted for publication elsewhere except as a brief abstract in the proceedings of a scientific meeting or symposium. Once you have prepared your submission in accordance with the Guidelines, manuscripts should be submitted online at rjmilmed@yahoo.com.

We look forward to your submission.

EDITORIAL AND CONTENT CONSIDERATIONS

Aims and Scope

Romanian Journal of Military Medicine (RJMM) is the official journal of the Romanian Association of Military Physicians and Pharmacists. The Journal publishes peer-reviewed original papers, reviews, meta-analyses and systematic reviews, and editorials concerned with clinical practice and research in the fields of medicine.

Papers cover the medical, surgical, radiological, pathological, biochemical, physiological, ethical and historical aspects of the subject areas.

Clinical trials are afforded expedited publication if deemed suitable. RJMM also deals with the basic sciences and experimental work, particularly that with a clear relevance to disease mechanisms and new therapies. Case reports and letters to the Editor will not be considered for publication.

Editorial Review and Acceptance

The acceptance criteria for all papers and reviews are based on the quality and originality of the research and its clinical and scientific significance to our readership. All manuscripts are peer reviewed under the direction of an Editor. The Editor reserves the right to refuse any material for review that does not conform to the submission guidelines detailed throughout this document, including ethical issues, completion of an Exclusive License Form and stipulations as to length.

ETHICAL CONSIDERATIONS

Principles for Publication of Research Involving Human Subjects

Manuscripts must contain a statement to the effect that all human studies have been reviewed by the appropriate ethics committee and have therefore been performed in accordance with the ethical standards laid down in an appropriate version of the Declaration of Helsinki (as revised in Brazil 2013), available at http://www.wma.net/en/30publications/10policies/b3/index.html. It should also state clearly in the text that all persons gave their informed consent prior to their inclusion in the study. Details that might disclose the identity of the subjects under the study should be omitted. Photographs need to be cropped sufficiently to prevent human subjects being recognized (or an eye bar should be used).

Registration of Clinical Trials

We strongly recommend, as a condition of consideration for publication, registration in a public trials registry. Trials register at or before the onset of patient enrolment. This policy applies to any clinical trial. We define a clinical trial as any research project that prospectively assigns human subjects to intervention or comparison groups to study the cause-and-effect relationship between a medical intervention and a health outcome. Studies designed for other purposes, such as to study pharmacokinetics or major toxicity (e.g., phase 1 trials) are exempt.

We do not advocate one particular registry, but registration with a registry that meets the following minimum criteria:

(1) Accessible to the public at no charge;
(2) Searchable by standard, electronic (Internet-based) methods;
(3) Open to all prospective registrants free of charge or at minimal cost;
(4) Validates registered information;
(5) Identifies trials with a unique number; and
(6) includes information on the investigator(s), research question or hypothesis, methodology, intervention and comparisons, eligibility criteria, primary and secondary outcomes measured, date of registration, anticipated or actual start date, anticipated or actual date of last follow-up, target number of subjects, status (anticipated, ongoing or closed) and funding source(s).

Plagiarism Detection

The journal employs a plagiarism detection system. By submitting your manuscript to this journal you accept that your manuscript may be screened for plagiarism against previously published works.

Committee on Publication Ethics

The journal subscribes to the principles of the Committee on Publication Ethics (COPE).

MANUSCRIPT CATEGORIES AND SPECIFICATIONS

All articles, with the exception of Editorials, must contain an abstract of no more than 250 words. Abstracts for original articles should be formatted into subheadings, as detailed below. Titles must not be longer than 120 characters (including spaces).

Editorials

These are invited by the Editor-in-Chief or their delegated editor, and should be a brief review of the subject concerned, with reference to and commentary about one or more articles published in the same issue of RJMM. Editorials are generally 1200–1500 words, may contain one table or figure and cite up to 15 references, including the source article [this should be cited as Military Med. Today (year); (vol): [this issue].

Review Articles

RJMM welcomes reviews of important topics across the scientific basis of medicine, and advances in clinical practice. Most published reviews are in response to editorial invitation, including thematically related "mini-series" of reviews. Authors considering submitting a review for RJMM are advised to canvas their possible review with the Editor-in-Chief or a colleague editor; this avoids early rejection if the subject matter is not deemed a high priority for the Journal at the time of submission. Reviews are limited to 3500–5000 words, with an abstract of up to 250 words and up to 75 references and 3–7 figures or tables.

Meta-Analyses or Systematic Reviews

RJMM particularly welcomes submission of Meta-Analyses and Systematic Reviews, which underpin evidence-based medicine. Guidelines for preparation of Meta-Analysis and Systematic Reviews are similar to other reviews, and articles are subject to the usual peer review process. Meta-Analyses and Systematic Reviews have a word limit of 3500–5000 words, with an abstract of up to 250 words and up to 75 references and 3–7 figures or tables.

Original Articles (including clinical trials)

RJMM welcomes original articles concerned with clinical practice and research in the fields of medicine. Papers can cover the medical, surgical, radiological, pathological, biochemical, physiological, ethical and/or historical aspects of the subject areas. Clinical trials are afforded expedited publication if deemed suitable. RJMM also deals with the basic sciences and experimental work, particularly that with a clear relevance to disease mechanisms and new therapies. Original articles are limited to 3000 words, with an abstract of up to 250 words and up to 50 references and 3–7 figures and tables.

Education and Imaging

The Editors welcome contributions to the Education and Imaging section. The purpose is to present imaging for the evaluation of unusual features of common conditions or diagnosis of unusual cases. Contributions will be reviewed by the Education and Imaging Coordinating Editors. The format of the Images pages involves two parts, each of which will occupy up to one journal page. In part 1, a case will be described briefly, including a summary of the presentation, clinical features and key laboratory results. One to two key images will then be presented. It is helpful to the reader if the author responds to questions that follow from the images of the case, such as 'What is your diagnosis? What are the features indicated on the CT scan? What is the differential diagnosis?' Part 2 will briefly describe the imaging features, particularly those that lead to diagnosis or which are critical for management. Differential diagnosis should be mentioned. It will be useful to include either further images or pathological details that validate the imaging diagnosis. Occasionally, presentation of analogous cases or related images from a similar case might be appropriate. Please include between one and three references to definitive studies and appropriate reviews of the subject. The format of the Images page involves a brief background to and description of the disorder of interest together with two figures of high quality. Colored photographs are encouraged. The submission may take the form of a case report or may illustrate particular features from more than one patient.

MANUSCRIPT PREPARATION

Style

Manuscripts should follow the style of the Vancouver agreement detailed in the International Committee of Medical Journal Editors' revised 'Uniform Requirements for Manuscripts Submitted to Biomedical Journals: Writing and Editing for Biomedical Publication', as presented at http://www.ICMJE.org/.

Spelling. The journal uses US spelling and authors should therefore follow the latest edition of the Merriam-Webster's Collegiate Dictionary.

Units. All measurements must be given in SI units as outlined in the latest edition of Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Royal Society of Medicine Press, London).

Abbreviations should be used sparingly and only where they ease the reader's task by reducing repetition of long technical terms. Initially use the word in full, followed by the abbreviation in parentheses. Thereafter use the abbreviation.

Trade names should not be used. Drugs should be referred to by their generic names, rather than brand names.

Parts of the Manuscript

The manuscript should be submitted in separate files: title page; main text file; figures.

Title page

The title page should contain (i) a short informative title that contains the major key words. The title should not contain abbreviations; (ii) the full names of the authors (if possible, not more than 5 authors per title); (iii) the author's institutional affiliations at which the work was carried out; (iv) the full postal and email address, plus telephone number, of the author to whom correspondence about the manuscript should be sent; (v) disclosure statement; and (vi) acknowledgements. The present address of any author, if different from that where the work was carried out, should be supplied in a footnote.

Disclosure statement

The source of financial grants and other funding should be acknowledged, including a frank declaration of the authors' industrial links and affiliations. In the case of clinical trials or any article describing use of a commercial device, therapeutic substance or food must state whether there are any potential conflicts of interest for each of the authors: failure to make such a statement may jeopardize the article being sent out for peer-review.

Acknowledgments

The contribution of colleagues or institutions should also be acknowledged. Thanks to anonymous reviewers are not allowed.

Main text

As papers are double-blind peer reviewed the main text file should not include any information that might identify the authors. The main text of the manuscript should be presented in the following order: (i) abstract and key words, (ii) text, (iii) references, (iv) tables (each table complete with title and footnotes), (vii) figure legends. Figures and supporting information should be submitted as separate files. Footnotes to the text are not allowed and any such material should be incorporated into the text as parenthetical matter.

Abstract and keywords

Original articles must have a structured abstract that states in 250 words or less the purpose, basic procedures, main findings and principal conclusions of the study. Divide the abstract with the headings: *Background and Aim, Methods, Results, Conclusions*. The abstracts of reviews need not be structured. The abstract should not contain abbreviations or references. Three to five keywords should be supplied below the abstract and should be taken from those recommended by the US National Library of Medicine's Medical Subject Headings (MeSH) browser—(http://www.nlm.nih.gov/mesh/meshhome.html).

Text

Authors should use subheadings to divide the sections of their manuscript: *Introduction, Methods, Results, Discussion Acknowledgments and References*.

References

The Vancouver system of referencing should be used. In the text, references should be cited using superscript Arabic numerals in the order in which they appear. If cited only in tables or figure legends, number them according to the first identification of the table or figure in the text. In the reference list, the references should be numbered and listed in order of appearance in the text. Cite the names of all authors when there are six or less; when seven or more list the first three followed by et al. Names of journals should be abbreviated in the style used in MEDLINE. Reference to unpublished data and personal communications should appear in the text only.

References should be listed in the following form:

Number references in the order cited as Arabic numerals in parentheses on the line. Only literature that is published or in press (with the name of the publication known) may be numbered and listed; abstracts and letters to the editor may be cited, but they must be less than 3 years old and identified as such. Refer to only in the text, in parentheses, other material (manuscripts submitted, unpublished data, personal communications, and the like) as in the following example: (Chercheur X, unpublished data). If the owner of the unpublished data or personal communication is not an author of the manuscript under review, a signed statement is required verifying the accuracy of the attributed information and agreement to its publication. Use Index Medicus as the style guide for references and other journal abbreviations. List all authors up to six, using six and "et al." when the number is greater than six.

Tables

Tables should be self-contained and complement, but not duplicate, information contained in the text. Number tables consecutively in the text in Arabic numerals. Type tables on a separate page with the legend above. Legends should be concise but comprehensive – the table, legend and footnotes must be understandable without reference to the text. Vertical lines should not be used to separate columns. Column headings should be brief, with units of measurement in parentheses; all abbreviations must be defined in footnotes. Footnote symbols: †, ‡, §, ¶ should be used (in that order) and *, **, *** should be reserved for *P*-values. Statistical measures such as SD or SEM should be identified in the headings.

Figure legends

Type figure legends on a separate page. Legends should be concise but comprehensive – the figure and its legend must be understandable without reference to the text. Include definitions of any symbols used and define/explain all abbreviations and units of measurement Indicate the stains used in histopathology. Identify statistical measures of variation, such as standard deviation and standard error of the mean.

Figures

All illustrations (line drawings and photographs) are classified as figures. Figures should be numbered using Arabic numerals, and cited in consecutive order in the text. Each figure should be supplied as a separate file, with the figure number incorporated in the file name.

Preparation of Electronic Figures for Publication: Although low quality images are adequate for review purposes, publication requires high quality images to prevent the final product being blurred or fuzzy.

SUBMISSION REQUIREMENTS

Manuscripts should be submitted online at rjmilmed@yahoo.com

A cover letter containing an authorship statement should be included.

The cover letter should include a statement covering each of the following areas:

1. Confirmation that all authors have contributed to and agreed on the content of the manuscript, and the respective roles of each author.
2. Confirmation that the manuscript has not been published previously, in any language, in whole or in part, and is not currently under consideration elsewhere.
3. A statement outlining how ethical clearance has been obtained for the research, particularly in relation to studies involving human subjects, and animal experimentation. The institutional ethics committees approving this research must comply with acceptable international standards (such as the Declaration of Helsinki) and this must be stated.
4. For research involving pharmacological agents, devices or medical technology, a clear Conflict of Interest statement in relation to any funding from or pecuniary interests in companies that could be perceived as a potential conflict of interest in the outcome of the research.
5. For clinical trials, that these have been registered in a publically accessible database.

If the above items are not included in the cover letter, manuscripts cannot be sent for review.

Please also note that the cover letter does not require a detailed or lengthy description of the content or structure of the manuscript itself.

Two Word-files need to be included upon submission: A title page file and a main text file that includes all parts of the text in the sequence indicated in the section 'Parts of the manuscript', including tables and figure legends but excluding figures which should be supplied separately.

The main text file should be prepared using Microsoft Word, doubled-spaced. The top, bottom and side margins should be 30 mm. All pages should be numbered consecutively in the top right-hand corner, beginning with the first page of the main text file.

Each figure should be supplied as a separate file, with the figure number incorporated in the file name. For submission, low-resolution figures saved as .jpg or .bmp files should be uploaded, for ease of transmission during the review process. Upon acceptance of the article, high-resolution figures (at least 300 d.p.i.) saved as .eps or .tif files will be required.

PUBLICATION PROCESS AFTER ACCEPTANCE

Accepted papers will be passed to production team for publication. The author identified as the formal corresponding author for the paper will receive an email, being asked to complete an electronic license agreement on behalf of all authors on the paper.

Accepted Articles

The accepted ‘in press’ manuscripts are published online very soon after acceptance, prior to copy-editing or typesetting. Accepted Articles are published online a few days after final acceptance, appear in PDF format only, are given a Digital Object Identifier (DOI), which allows them to be cited and tracked. After print publication, the DOI remains valid and can continue to be used to cite and access the article. Given that copyright licensing is a condition of publication, a completed copyright form is required before a manuscript can be processed as an Accepted Article.

Proofs

Once the paper has been typeset, the corresponding author will receive an e-mail alert containing instructions on how to provide proof corrections to the article. It is therefore essential that a working e-mail address is provided for the corresponding author. Proofs should be corrected carefully; the responsibility for detecting errors lies with the author. The proof should be checked, and approval to publish the article should be emailed to the Publisher by the date indicated; otherwise, it may be signed off on by the Editor or held over to the next issue.

Offprint

A PDF reprint of the article will be supplied free of charge to the corresponding author. Additional printed offprint may be ordered for a fee.

COPYRIGHT, LICENSING AND ONLINE OPEN

Details are on the Copyright Agreement Form that must be completed and signed when the Article is accepted.

21 AUGUST - ZIUA MEDICINEI MILITARE

Şeful DIRECŢIEI MEDICALE
Col. medic conf. univ. dr. Marian MACRI

La 21 august 2007, se împlinesc 145 de ani de când, prin **Înaltul Decret Domnesc nr. 4629/21.08.1862**, semnat de Domnitorul Alexandru Ioan Cuza, a fost instituit *Corpul ofiţerilor sanitari ai armatei* şi *Direcţia Generală a Serviciului Sanitar Român*. S-a constituit astfel, cu începere din anul 1862, un organism specializat menit să asigure păstrarea sănătăţii efectivelor armatei române.

Încă de la începuturile ei, medicina militară a beneficiat de profesionalismul şi calităţile generalului de divizie medic dr. Carol Davila adus în ţară de Domnitorul Gheorghe Bibescu în anul 1852, care avea o împătrită responsabilitate: inspector general al serviciului sanitar al armatei, director al Şcolii de Medicină (întemeietorul învăţământului medico-militar şi medical superior din ţara noastră), inspector al adminstraţiei centrale sanitare şi efor al spitalelor.

Elaborarea *"Instrucţiunilor pentru funcţionarea ambulanţelor"* şi *"Deciziei relative la serviciul ambulanţelor în armată"* , precum şi promulgarea prin **Înaltul Decret nr. 1125/15.04.1882** a *„Legii pentru organizarea Serviciului Sanitar al Armatei"* au creat cadrul legislativ de funcţionare a serviciului sanitar militar, condus de o direcţie proprie în cadrul Ministerului de Război.

În decursul anilor, personalul medico-sanitar al armatei a devenit un corp de elită al medicinei româneşti, remarcându-se prin realizări importante în apărarea sănătăţii militarilor şi prin contribuţii însemnate la progresul ştiinţei şi practicii medicale.

Personalul medico-sanitar al Armatei României, dovedind profesionalism şi spirit de sacrificiu, s-a implicat în toate momentele cruciale ale istoriei poporului român începând cu Războiul de Independenţă, continuând cu Războiul de întregire naţională, Al doilea război mondial şi Revoluţia din Decembrie 1989.

Rezultatele obţinute pe tărâmul luptei cu moartea în campaniile menţionate, precum şi numeroasele jertfe din rândul personalului medico-sanitar motivează respectul oştirii şi al poporului nostru pentru serviciul medical al armatei, ai cărui eroi şi-au câştigat un binemeritat loc în rândul martirilor neamului.

Participările medicinei militare la misiunile de asistenţă umanitară sub egida O.N.U. din Somalia şi Angola, precum şi la suportul medical al misiunilor din cadrul Parteneriatului pentru Pace din Albania şi Bosnia, la misiunile sub egida NATO din Afganistan şi Irak, au evidenţiat profesionalismul şi devotamentul personalului medico-sanitar, capacitatea acestuia de cooperare cu structuri multinaţionale similare în soluţionarea problemelor de specialitate, făcând cunoscute valoarea medicinei naţionale şi încărcătura umană a activităţii medicale.

Cu toate că, potrivit concepţiei militare, medicina militară trebuie să se îndrepte spre specializări utile în timp de răboi şi situaţii de criză, foarte mulţi medici militari au abordat şi specialităţi deosebit de utile în timp de pace. Medicii militari de toate specialităţile au lucrat intens, susţinut şi cu eficienţă, devenind personalităţi recunoscute de lumea medicală internă şi internaţională. Mulţi medici militari au fost cooptaţi în învăţământul universitar medical devenind profesori, conferenţiari şi şefi de lucrări în Universitatea de Medicină şi Farmacie „Carol Davila" din Bucureşti, precum şi în alte facultăţi de profil din ţară, formând numeroşi specialişti şi chiar adevărate şcoli medicale naţionale, recunoscute şi pe plan internaţional. Totodată, o mare parte din aceşti specialişti ocupă funcţii în structurile de conducere în cadrul unor societăţi şi asociaţii profesionale interne şi internaţionale.

Medicina militară, dispunând de un corp medical de elită, s-a putut organiza şi păstra ca entitate remarcabilă de-a lungul anilor, rezistând tuturor greutăţilor şi vicisitudinilor vremurilor. Totodată, de-a lungul timpului, medicii militari au dovedit că reprezintă un corp de profesionişti solidar care şi-a cunoscut rolul şi menirea, manifestându-se ca autentice valori ale medicinei româneşti.

Începând cu anul 2001, reţeaua de medicină militară, asemenea întregii armate, cunoaşte un amplu proces de restructurare şi modernizare, început de la nivel central şi continuând la nivelul structurilor de execuţie – formaţiunile de asistenţă medicală -, proces continuu care urma să realizeze o intergrare cât mai concretă şi eficientă în sistemul naţional de asistenţă medicală bazat pe asigurările sociale de sănătate.

Astfel reorganizate, în concordanţă cu sistemul naţional de asigurări de sănătate şi cu reducerea efectivelor armatei, structurile noastre medico-militare au putut acoperi cerinţele tuturor solicitanţilor de servicii de sănătate – personalul armatei, pensionarii militari, veteranii de război -, au intervenit cu promptitudine, eficienţă şi eficacitate în situaţii deosebite (dezastre naturale, accidente tehnologice) şi au capacitatea ca în situaţii de criză şi/sau campanie să acorde asistenţă medicală de calitate trupelor, dând dovadă de manevrabilitate, maleabilitate şi fiabilitate.

Relaţiile de colaborare cu serviciile sanitare ale armatelor membre sau partenere NATO s-au dezvoltat şi diversificat, medicii militari şi formaţiunile medicale militare participând la exerciţii NATO/PfP, atât pentru organizarea şi conducerea acestora, cât şi pentru asigurarea asistenţei medicale reale.

Serviciile de sănătate puse la dispoziţia utilizatorilor de către formaţiunile medicale ale armatei se dezvoltă şi diversifică continuu pentru a putea face faţă concureţei altor prestatori de servicii din domeniul sanitar, proces obiectiv în beneficiul populaţiei, stabilit de sistemul asigurărilor sociale de sănătate în România, prevăzut de Legea nr. 95/2006 privind reforma în sănătate.

În strictă corelare cu aplicarea prevederilor Legii nr. 95/2006 trebuie depuse în continuare eforturi din partea tuturor factorilor de decizie direct implicaţi în transpunerea în practică a conţinutului Legii nr. 80/1995, privind statutul cadrelor militare, în special pentru asigurarea resurselor financiare necesare acordării medicamentelor gratuit în tratamentul ambulatoriu al beneficiarilor acestei legi, atât din fondul asigurărilor sociale de sănătate cât şi din bugetul M.Ap.

Anul 2007 aduce după sine noua Concepţie privind reorganizarea şi modernizarea sistemului medical militar, agreată de conducerea politică şi militară a ţării, conform căreia sarcinile specifice unităţilor şi formaţiunilor medicale în timp de pace se împletesc în mod firesc, necesar cu cele care privesc medicina operaţională, de campanie. În acest sens urmează ca pentru 6 spitale militare de urgenţă să se înfiinţeze servicii de medicină operaţională ce vor asigura resursele umane calificate pentru participarea cu eficienţă la misiunile ordonate în afara ţării.

Tradiţiile cu care medicina militară se mândreşte, ne obligă să ne angajăm cu toate forţele pentru îmbunătăţirea continuă a stării de sănătate a militarilor, pentru menţinerea capacităţii combative a armatei.

La aniversarea Zilei medicinei militare doresc să vă adresez felicitări şi urarea ca, prin abnegaţie, pricepere şi dăruire în muncă, să obţineţi rezultate cât mai bune în alinarea suferinţelor semenilor noştri, pentru formarea unor militari sănătoşi, permanent în măsură să facă faţă condiţiilor severe ale câmpului de instrucţie sau ale misiunilor pe care le au de îndeplinit.

MESAJUL
ŞEFULUI STATULUI MAJOR GENERAL

CU PRILEJUL ZILEI MEDICINEI MILITARE
- 21 AUGUST 2007 –

La 21 august 2007 sărbătorim 145 de ani de la înfiinţarea primelor structuri medicale în Armata României – Corpul ofiţerilor sanitari ai armatei şi Direcţia Generală a Serviciului Sanitar Român.

Beneficiind pe întreaga durată a existenţei de aportul unor corifei ai domeniului, medicina militară şi-a căpătat rapid un loc de cinste în conştiinţa militarilor români. Corpul medical al Armatei României şi-a dovedit calităţile profesionale, ştiinţifice şi umane de excepţie pe parcursul tuturor conflagraţiilor la care a participat, dând adevărate pilde de eroism în lupta cu rănile şi cu bolile necruţătoare ale acelor timpuri.

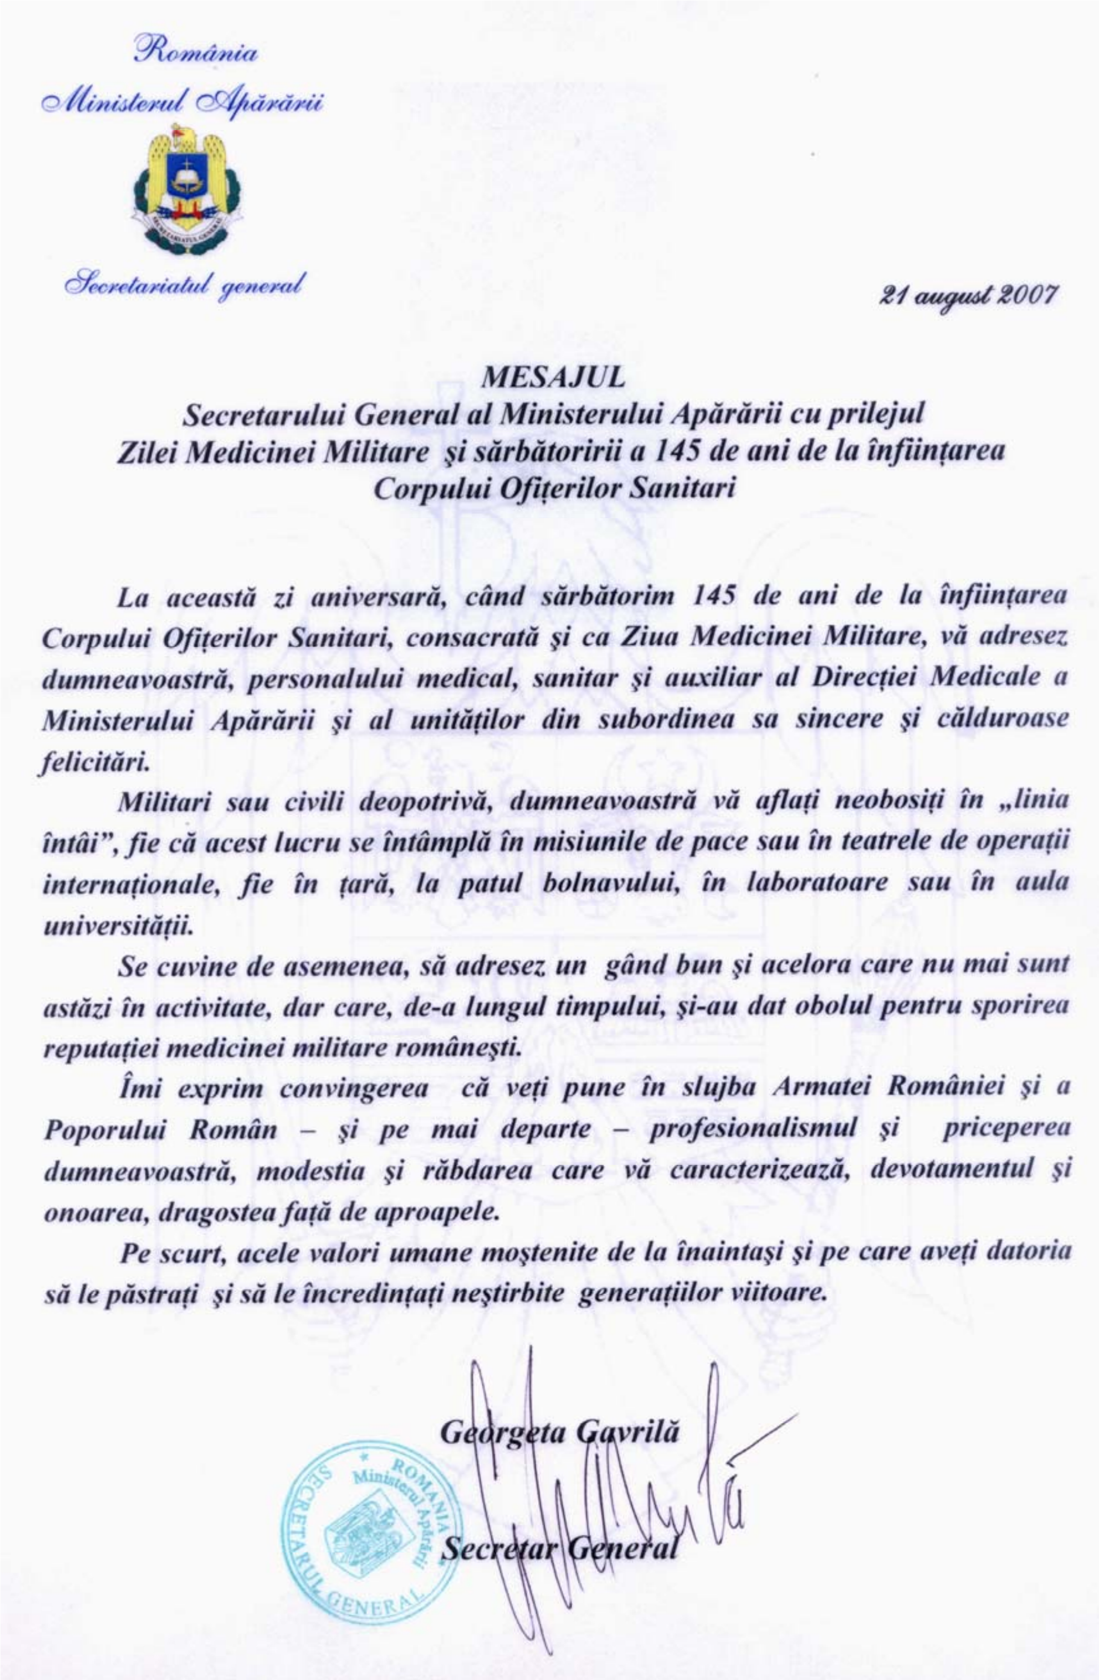
Spitalele militare organizate pe întreg teritoriul ţării şi-au probat pe parcursul a mai bine de un secol renumele de instituţii medicale de prim rang, apreciate ca atare de militarii activi, în rezervă sau în retragere, de familiile lor şi de toţi cetăţenii, care au găsit în acestea un loc de alinare a suferinţelor şi de redare a speranţei într-o viaţă liniştită şi fără dureri. Personalul medical din unităţi s-a distins printr-o conduită demnă, contribuind la dimensiunea profilactică a actului medical şi constituind întotdeauna interfaţa dintre militari şi instituţiile specializate.

Medicii militari au fost în permanenţă în avangarda specialiştilor în domeniu, de numele şi activitatea lor fiind legate nenumărate descoperiri ştiinţifice, lucrări şi tratate de specialitate, o activitate universitară laborioasă, pusă în slujba profesiei şi a oştirii.

Asemenea întregii armate, medicina militară trece în prezent printr-un proces de reorganizare şi restructurare, menit să o plaseze la nivelul cerinţelor unui sistem militar modern, urmând să fie în măsură să răspundă la standarde ridicate rigorilor profesionale şi ştiinţifice ale momentului, pentru a-şi îndeplini menirea.

Iată de ce, astăzi, în zi aniversară, mă înclin cu admiraţie în faţa memoriei celor care au pus bazele medicinei militare româneşti şi a urmaşilor lor, demni membri ai clubului select al celor pentru care viaţa umană este bunul suprem. Adresez sincerele mele urări de bine şi sănătate tuturor medicilor, asistenţilor şi personalului medical auxiliar din armată şi le urez să aibă parte numai de succese în bătălia nobilă pentru redarea speranţei într-o viaţă sănătoasă a tuturor celor care apelează la serviciile lor.

ŞEFUL STATULUI MAJOR GENERAL
Amiral dr.
Gheorghe MARIN



România
Ministerul Apărării
Secretariatul general

21 august 2007

MESAJUL
Secretarului General al Ministerului Apărării cu prilejul Zilei Medicinei Militare şi sărbătoririi a 145 de ani de la înfiinţarea Corpului Ofiţerilor Sanitari

La această zi aniversară, când sărbătorim 145 de ani de la înfiinţarea Corpului Ofiţerilor Sanitari, consacrată şi ca Ziua Medicinei Militare, vă adresez dumneavoastră, personalului medical, sanitar şi auxiliar al Direcţiei Medicale a Ministerului Apărării şi al unităţilor din subordinea sa sincere şi călduroase felicitări.

Militari sau civili deopotrivă, dumneavoastră vă aflaţi neobosiţi în „linia întâi”, fie că acest lucru se întâmplă în misiunile de pace sau în teatrele de operaţii internaţionale, fie în ţară, la patul bolnavului, în laboratoare sau în aula universităţii.

Se cuvine de asemenea, să adresez un gând bun şi acelora care nu mai sunt astăzi în activitate, dar care, de-a lungul timpului, şi-au dat obolul pentru sporirea reputaţiei medicinei militare româneşti.

Îmi exprim convingerea că veţi pune în slujba Armatei României şi a Poporului Român – şi pe mai departe – profesionalismul şi priceperea dumneavoastră, modestia şi răbdarea care vă caracterizează, devotamentul şi onoarea, dragostea faţă de aproapele.

Pe scurt, acele valori umane moştenite de la înaintaşi şi pe care aveţi datoria să le păstraţi şi să le încredinţaţi neştirbite generaţiilor viitoare.

Georgeta Gavrilă

Chistul bronhogenetic cu localizare rară

Dr. SAVU C[*].,Dr. NICA Angelica, Dr. PIRVU A.

Chistul bronhogenetic este o leziune congenitală, întâlnită cel mai frecvent la nivelul mediastinului şi care se dezvoltă din regiunea şanţului laringotraheal. În majoritatea cazurilor este asimptomatic, simptomele care apar în evoluţie fiind determinate de complicaţiile pe care le determina asupra organelor din jur. Tratamentul de electie este cel chirurgical prin excizia completă a formaţiunii, pentru prevenirea recidivelor.

chist bronhogenetic chirurgie excizia

ABSTRACT

The bronchogenic cyst is a congenital disease, who is developed the most freqvently in the mediastinum from laringotracheal sulcus. In the most comun cases it has nosigns or simptoms. The clinical findings are caused by complication of this disease and the impact of surroundings organs. The treatment of choice is surgery with completely excision for prevents recurrences.

KEY WORDS: bronchogenic cyst, surgery

Chistele intratoracice sunt cele mai comune leziuni întâlnite la copii şi adulţi. Majoritatea sunt leziuni congenitale şi ocupa 20-32% din masele primare mediastinale. Jumătate sau chiar mai mult din acestea nu sunt identificate până în decada a 3-a sau a 4-a de viaţă (32% sunt descoperite înainte de 20 ani şi 68% după 20 ani). Clasificare lor se bazează pe etiologie, pe caracteristicile histologice şi embriologice.

CLASIFICARE

1. Congenitale – chiste mezoteliale, chiste dezvoltate din intestinul bronhogenic, chiste limfatice
2. Dobândite: inflamatorii, timice, teratogene, dermoide, dezvoltate din tiroida şi paratiroide, chistul hidatic.

EMBRIOGENEZA: Chistul bronhogenetic are ca punct de plecare sechestrarea celulelor din regiunea şanţului laringotraheal în timpul dezvoltării embriologice timpurii. În săptămâna a 3-a a gestaţiei, şanţul laringotraheal sau sistemul respirator primitiv se dezvolta în partea anterioară a intestinului primitiv, sub forma unui diverticul, situat caudal de punga faringiană.

Acest diverticul se transforma mai târziu într-un tub care devine arborele bronşic primitiv. După săptămâna a 4-a, apar distal 2 proeminente, care devin viitoarele bronşii şi mugurele pulmonar. În ziua a 35-a apare bronşia lobară. Înmugurirea anormală a arborelui bronşic poate conduce la mase chistice traheale şi bronşice numite chiste bronhogenetice.

Când aceasta înmugurire anormală apare devreme în timpul gestaţiei, chistele au tendinţa să se localizeze la nivelul mediastinului şi rareori comunică cu arborele bronşic. Chistele ce se dezvoltă mai târziu sunt mai periferice şi localizate în parenchimul pulmonar. Acestea comunică adesea cu bronşiile.

---

[*] Spitalul Clinic de Urgenta Militar Central – Secţia Chirurgie Toracică

Majoritatea chistelor bronhogenetice sunt în strânsă relație anatomică cu arborele bronşic, sau esofagul, în compartimentul visceral al mediastinului, ocazional se pot extinde sub diafragm.
Coselli şi colaboratorii au descris chiste bronhogenetice localizate în întregime în abdomen în regiunea cozii pancreasului.

HISTOLOGIE

Chisturile bronhogenetice sunt tapetate de un epiteliu ciliat columnar sau cuboid, unistratificat, având la baza fibre musculare netede. Mucoasa epiteliala poate suferi metaplazie scuamoasă. Când se produce infecția secundară, epiteliul poate fi distrus şi apare puroiul franc. Peretele chistului este subțire şi conține cartilaje hialine, glande bronşice, celule musculare netede si trunchiuri nervoase. Conținutul poate fi: lichidian clar, hemoragic, mucos, purulent.
În general, chisturile bronhogenetice sunt unice, dar pot fi şi multiloculare sau multiple.

LOCALIZARE

După Maier exista 5 localizari: 1-paratraheal, 2-carinal, 3-hilar, 4-paraesofagian si 5-variate. Raportat la bifurcația traheei ca linie de diviziune, s-a constatat ca 23% din chisturile bronhogenetice. sunt localizate deasupra carinei şi 77% distal de aceasta. După Roughly, o treime sunt situate în mediastinul mijlociu şi 2/3 in mediastinul posterior.
Localizări rare: mediastinul anterior, cavitatea pericardica, şanțul paravertebral, parenchimul pulmonar, ligamentul triunghiular, intratimic, subcutanat, presternal, supraclavicular, regiunea scapulară, transdiafragmatic şi chiar abdominal. Coselli sugerează ca aceste chiste rezultă din înmugurirea anormală a canalului primitiv care migrează în abdomen înainte de fuziunea cu membrana pleuroperitoneală.

Referitor la parenchimul pulmonar, mai frecvent, chistul bronhogenetic se întâlneşte la nivelul lobilor inferiori. Cu toate acestea, după Ribet şi colaboratorii, din 21 de cazuri de chist bronhogenetic la sugari şi copii, lobul superior drept şi lobul superior stâng au fost implicați fiecare în 7 cazuri, lobul inferior stâng în 6 cazuri şi lobul inferior drept într-un caz.

PATOLOGIE

20% din copii sunt asimptomatici. După Ribet şi colaboratorii, la 4 din pacienții lor, chistul bronhogenetic a fost identificat prin ultrasonografie prenatală. Chistele parenchimatoase comunică frecvent cu arborele traheobronsic şi de obicei prezintă semne de sepsis pulmonar.
La adulți, frecventa este mai mare la bărbați decât la femei. În general sunt asimptomatici. Peste jumătate devin simptomatici prin compresia căilor aeriene, a esofagului sau prin prezenta infecțiilor. Acestea din urma pot fi cauzate de perforația în fiecare din structurile învecinate, dar infecția apare cel mai des fără astfel de comunicații. După Sirivella 16 din 20 pacienți sunt simptomatici şi prezintă: tuse, dispnee, disfagie şi durere toracică. Simptome mai rar întâlnite sunt: febra, sputa purulenta, anorexia şi pierderea în greutate, hemoptizia.

În studiile efectuate de St-George şi colaboratorii, cel mai comun simptom a fost durerea substernală, care rezulta din iritația sau inflamația pleurei parietale sau mediastinale înconjurătoare.
Disfagia, dispneea şi tusea sunt date de compresia sau iritația bronşiilor sau esofagului de către chist.

Expectorația purulenta e dată de infectarea chistului, cu fistulizare sau mai probabil, de pneumonia din plămânul adiacent comprimat.

CAZ CLINIC

Pacienta C.S., în vârstă de 39 ani, nefumătoare, din mediu urban, având ca antecedente personale patologice: tiroidectomie totală pentru guşă polinodulara (efectuată în 2005 şi sub tratament cu Eutyrox 100µg), mixedem posttiroidectomie, hipoparatiroidism secundar iatrogen, histerectomie subtotală pentru fibrom uterin (2005), mastoza fibrochistica bilaterală, apendicectomie şi sechele fibronodulare pulmonare bilaterale, se internează în clinica noastră pentru: disfagie pentru solide şi lichide, dispnee de efort, astenie fizică marcată, scădere ponderală (6-7 kg în ultimele 2 luni), inapetența, fatigabilitate.

Examenul obiectiv pe aparate şi sisteme a fost in limite normale (pacienta subponderala).

Pe perioada internării s-au efectuat următoarele investigații: EKG- tahicardie sinusală; Ecografie cardiacă: Aorta inițiala-3,SIV-9, FE=60%; Consultul cardiologic a decelat prezenta unui prolaps de valva mitrală posterioară. Analizele hematologice au evidențiat: hemograma cu uşoară trombocitoza (441000/mmc), biochimie şi coagulograma normale, fibrinogen crescut (590,3mg/dl).

Pe radiografia pulmonară de față şi profil s-au remarcat leziuni fibronodulare bilaterale.

Endoscopia digestivă superioară nu a decelat modificări, cu excepția unei hernii gastrice transhiatale de dimensiuni mici.

Ecoendoscopia a pus in evidență o formațiune de aproximativ de 60,5/27mm, situată în mediastinul posterior, între aorta descendenta şi cord, care vine în contact cu pleura şi care nu pare sa o invadeze, cu conținut intens hipoecogen, relativ omogena, fără adenopatii peritumorale.(fig. 1)

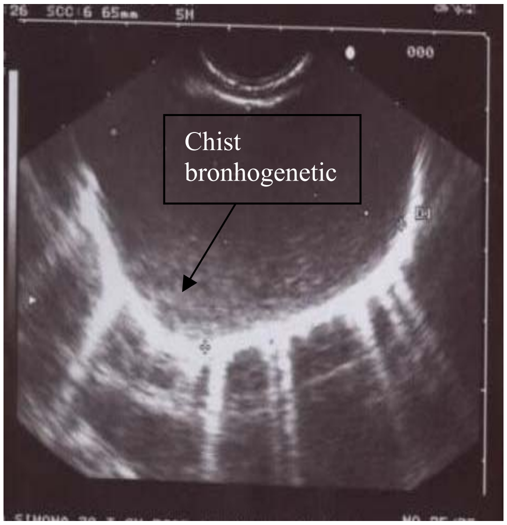

Fig.1.Ecoendoscopie.

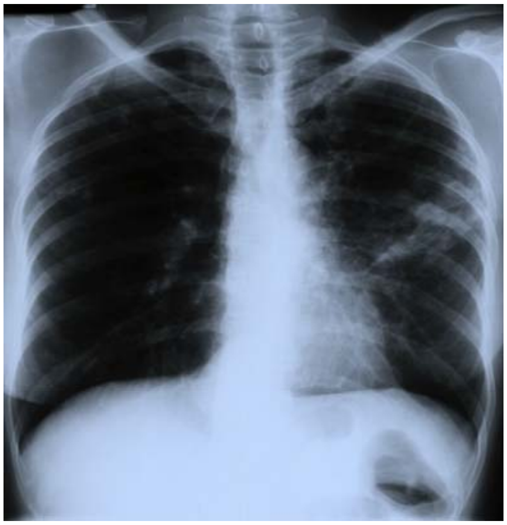

Fig.2.Radiografie toracica.

Concluzii: formațiune tumorală de mediastin posterior în observație etiologica (leiomiom, adenopatie giganta).

Tomografia computerizată cu substanță de contrast a evidențiat: formațiune hipodensă, omogena, neiodofila, ovalară, cu dimensiuni axiale de 5/3,2 cm, fără acumulare de contrast oral, situată în partea inferioară a toracelui drept, paraesofagian, compresivă moderat pe structura pleuropulmonară adiacenta; îndeosebi pe fereastra de parenchim, leziuni fibronodulare ce ocupa teritoriul apicodorsal al lobului superior stâng şi lingula; aceleaşi modificări, mai puțin extinse, dorsal în lobul superior drept şi în segmentul Fowler stâng; organele abdomenului superior în limite normale.

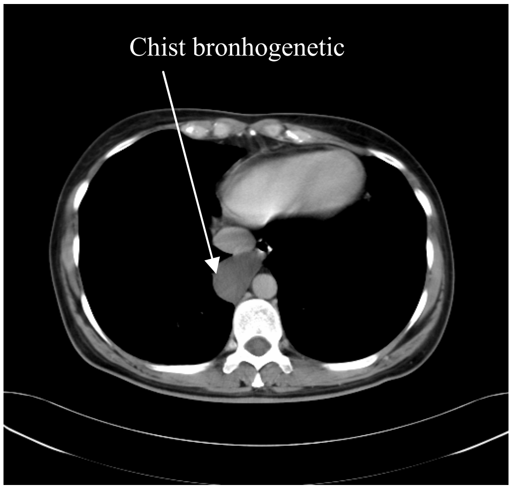

Fig.3 CT toracic

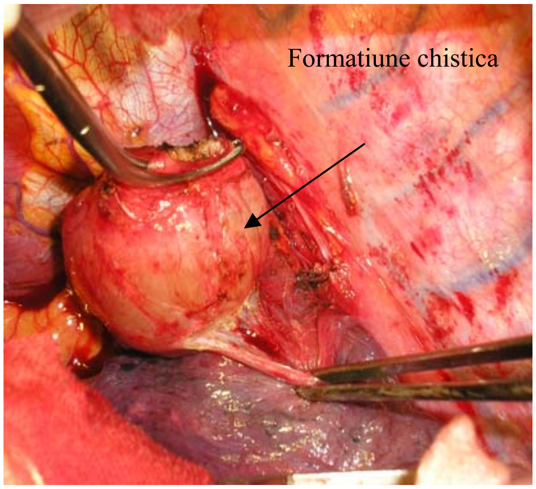

Fig. 4 Aspect intraoperator

Concluzii: formațiune chistică paraesofagiană dreapta, cu apartenența la structurile mediastinale posterioare (tumora neurala, chist de canal toracic) (fig.3).

Tranzitul baritat a descris: esofag normal, stomac alungit, hipoton, hipokinetic, cu polul inferior sub crestele iliace, pliuri ale mucoasei îngroşate, pilor permeabil, bulb duodenal normal, cadru duodenal normal.

În urma coroborării datelor clinice şi paraclinice s-a decis efectuarea intervenției chirurgicale şi s-a practicat chistectomie ideala (protocol operator nr.360/26.04.2007). S-a practicat toracotomie postero-laterala dreapta cu acces în cavitatea pleurală prin spațiul VII intercostal. La inspecție s-a constatat o formațiune chistica, cu diametre de 6/4 cm, localizată în mediastinul posterior şi dezvoltată paraesofagian, în ligamentul triunghiular, între aorta toracică şi vena cavă inferioară, înconjurată de parenchimul lobului pulmonar inferior drept. S-a disecat formațiunea de țesuturile învecinate şi s-a practicat chistectomie ideala(fig.4). Acest tip de localizare este rar întâlnită. Drenaj pleural cu 2 tuburi de dren 26CH şi 28CH cuplate la aspirație activă.

Evoluția postoperatorie a fost lent favorabilă prin persistenta pierderilor aeriene şi expansionare pulmonară lentă.

Examen histopatologic: perete chistic tapetat de un epiteliu de tip respirator şi cu glande de tip bronşic şi țesut muscular neted, aspect compatibil cu chistul bronhogenetic.

DISCUȚII

În studiul lui St-George 18 pacienți au avut chiste complicate, documentate atât la examinarea macroscopica cât şi la cea histopatologică, dar în nici una din aceste complicații nu au rezultat suferințe majore. În chistele bronhogenetice pot apare complicații mecanice date de compresia chistului asupra structurilor învecinate (vase mari, esofag, pericard, plămân, bronşii, etc).

Complicațiile cardiovasculare sunt rare. Watson şi Chaudhary citează 1 pacient cu tahicardie atrială şi ventriculară. Volpi şi colaboratorii raportează apariția fibrilației atriale paroxistice, data de compresiunea pe atrii. Watson şi Berkowits descriu compresia arterei pulmonare ce simulează stenoza arterei, Selke şi colaboratorii descriu compresia arterei pulmonare de lungă durată dată de artera pulmonară hipoplazica şi plămânul hiperlucent.

Sindromul de vena cavă superioară a fost întâlnit într-un singur caz.

Complicații infecțioase sunt reprezentate de inflamația peretelui chistic cu sau fără ulcerații ale mucoasei fiind întâlnită în 18% din cazuri.

Această descoperire a fost adesea asociată cu durerea toracica. Infecția bacteriană (pozitivată) a fost rară. Comunicarea franca cu arborele traheobronşic a fost întâlnită la 3 pacienți care prezentau dispnee, febră şi tuse productivă.

Comunicarea cu esofagul şi cavitatea pericardică nu a fost observată. Moor şi Jahnke au observat (ocazional) la chistele, a căror mucoasă prezenta epiteliu gastric, simptome legate de secreția acidă intrachistică.

Spock şi colaboratorii au descris apariția hemoragiei intrachistice exteriorizate prin hematemeza sau hemoptizie acestea fiind complicații hemoragice.

Riscul malignizarii este minim, s-a citat degenerarea în carcinom şi fibrosarcom. Greenfield şi Howe în 1965 şi Bemnheim şi colaboratorii în 1980 au descris transformarea în leiomiosarcom, dar se presupune că dezvoltarea s-a produs din peretele chistului. S-au citat şi asocieri cu tumori maligne: rabdomiosarcom, adenocarcinom, carcinom scuamos.

Cazul prezentat de noi a ridicat o serie de probleme de diagnostic diferențial cu: abcesul pulmonar (prezintă sindrom infecțios şi are perete gros), chistul hidatic (perete propriu), tumori chistice mediastinale (disgerminoame, chiste pericardice), tumori rare (chistadenocarcinom), leziuni traumatice (hematomul), tumori esofagiene extramucoase.

CONCLUZII

Atitudinea de expectativa nu se recomandă, chiar dacă chistul bronhogenetic este asiptomatic.

Procedura de electie este excizia completă, deoarece rezecția parțială sau aspirația chistului duc la recidivă. Se recomandă denudarea mucoasei chistului de pe structurile vitale, în condițiile în care nu se poate efectua rezecția completă.

Intervenția se poate efectua prin toracoscopie, chirurgie toracică videoasistată sau clasic. În funcție de localizarea chistului se recomandă toracotomie postero-laterala (pentru chistele localizate în mediastinul posterior) sau sternotomie (pentru chistele situate în compartimentul anterior al mediastinului).

Ginsberg a publicat un caz rezecat prin mediastinoscopie.

Avantajele chirurgiei toracice videoasistate: diminuarea durerii postoperatorii, durata scăzută a spitalizării, reintegrarea rapidă a pacientului în activitate.

Morbiditatea postoperatorie este scăzută prin complicații minime, mortalitatea zero.

Factorii de risc în bolile cerebro-vasculare

Colonel (r) dr. IOAN AXINTE[*]
Dr. ROXANA-ELENA MIHALCEA[**]

REZUMAT: Factorul de risc se defineşte în sens general ca orice condiţie sau caracteristică ce poate prevedea în cazul unui subiect, posibilitatea apariţiei unor boli manifeste clinic. Are prin urmare o semnificaţie predictivă. O altă definiţie este de factori ai ecosistemului uman care influenţează negativ starea de sănătate. Factorii de risc în bolile cerebro-vasculare pot fi majori (fundamentali, primari), adjuvanţi (favorizanţi) şi precipitanţi (declanşatori).

factori de risc majori adjuvanţi precipitanţi

ABSTRACT: The risk factor is generally defined as any condition or feature which can anticipate the possibility of the appearance of some clinical symptoms at patients. Therefore, it has a significance that can be predicted. Another definition is that of the elements of the human ecosystem which influence, in a negative way, the health condition. The risk factors in brain-vascular diseases can be very important (vital, primary), adjuvant and precipitant (activating).

Multiple date culese în urma studiilor epidemiologice au dus la elaborarea conceptului „factorului de risc” în bolile cerebro-vasculare, care prezintă în momentul actual importante implicaţii practice şi teoretice privind etiologia, patogenia şi prevenirea bolilor cerebro-vasculare. Am putea defini „factorul de risc” în bolile cerebro-vasculare, o deviere de la normal sau o afecţiune, care, evidenţiată la o persoană fără manifestări clinice, se asociază cu o probabilitate crescută de apariţie a bolilor cerebro-vasculare în viitorul mai apropiat sau mai îndepărtat.

Prin prezenţa unuia sau a mai multor factori de risc se poate evalua chiar cantitativ gradul de probabilitate pentru o persoană să facă o boală cerebro-vasculară. În acest fel suntem „susceptibili” de a face o boală cerebro-vasculară.

Prin analiza diverselor studii epidemiologice ca şi prelucrarea datelor statistice din studiul personal, se evidenţiază un număr mare de factori de risc care pot fi implicaţi direct sau indirect în producerea bolilor cerebro-vasculare sau pot reprezenta o relaţie statistică semnificativă cu incidenţa bolilor cerebro-vasculare: hipertensiunea arterială, ateroscleroza, dislipidemiile, diabetul zaharat, bolile cardiace (îndeosebi fibrilaţia atrială şi cardiopatia ischemică), alcoolismul, fumatul, obezitatea, ereditatea, bolile hematologice, malformaţiile vasculare intracraniene.

Rolul altor factori de risc este nesigur sau nedovedit concret: hiperuricemia, discriniile, sedentarismul, particularităţi constituţionale individuale, infecţiile, neoplaziile, radiaţiile, contraceptivele orale, substanţele psiho-active, cafeaua.

Ierarhizarea factorilor de risc privind importanţa lor în producerea bolilor cerebro-vasculare nu este uşoară şi cere încă studii suplimentare, dar este necesară pentru a putea constitui o bază de pornire în elaborarea unui program vast de prevenire şi combatere a bolilor cerebro-vasculare. Pe baza studiilor epidemiologice internaţionale, naţionale şi personale este posibil să conchidem că unii dintre factorii de risc au o relaţie primară cu bolile cerebro-vasculare şi putem să-i numim majori (fundamentali), în timp ce alţii ar juca un rol adjuvant (favorizant), iar alţii au un rol precipitant (declanşator).

---

[*] Compartimentul de Psihiatrie, Spitalul Militar de Urgenţă Timişoara

[**] Clinica de Psihiatrie Eduard Pamfil Timişoara, Spitalul Clinic Judeţean de Urgenţă nr. 1 Timişoara

Factorii de risc majori (fundamentali, primari) în bolile cerebro-vasculare sunt: hipertensiunea arterială, ateroscleroza, dislipidemiile, bolile cardiace, diabetul zaharat, bolile hematologice, malformaţiile vasculare intracraniene, fumatul.

Factorii de risc adjuvanţi (favorizanţi, agravanţi) sunt: obezitatea, sedentarismul, istoricul familial (ereditatea), colagenozele, alcoolul, cafeaua, contraceptivele orale, discriniile, uricemia, solicitarea socio-profesională, neoplaziile, radiaţiile, substanţele psiho-active, vârsta, sexul.

Factorii de risc precipitanţi (declanşatori) sunt: salturile tensionale, infecţiile, excesele izolate sau combinate, suprasolicitarea socio-profesională, temperaturile extreme.

Factorii care au o relaţie primară sau favorizantă cu bolile cerebro-vasculare trebuie să fie prezenţi şi activi o perioadă lungă de timp, pentru a-şi produce efectul. Factorii precipitanţi (declanşatori) pot fi de scurtă durată de ordinul minutelor sau orelor. În absenţa factorilor majori (primari), factorii adjuvanţi (favorizanţi) singuri nu măresc semnificativ incidenţa şi prevalenţa bolilor cerebro-vasculare.

Datele studiilor Framingham au dus la conturarea unui profil de risc cerebro-vascular, care include 5 factori de risc întâlniţi la 10% din populaţia asimptomatică şi care determină ⅓ până la ½ din accidentele vasculare cerebrale: hipertensiunea arterială, hipercolesterolemia, toleranţa la glucoză anormală, dar nu diabetul, fumatul, hipertrofia ventriculară stângă.

Prezenţa tuturor factorilor creşte riscul de accident vascular cerebral de 8 ori. Trecerea în revistă a factorilor de risc în accidentele vasculare cerebrale evidenţiază ponderea hipertensiunii arteriale la toate vârstele şi la ambele sexe.

Temperaturile extreme (caniculă-ger) şi variaţiile mari şi rapide de temperatură constituie de asemenea un factor de risc, deşi nu există studii bine fundamentate. Din practica medicală s-a remarcat că acestea pot acţiona ca factori declanşatori ai unui accident vascular cerebral hemoragic sau ischemic.

Un studiu clinic şi paraclinic de Kory Calomfirescu şi colaboratorii referitor la factorii de risc în accidentele vasculare cerebrale (ischemice şi hemoragice) pe un lot de bolnavi până la 40 de ani a evidenţiat faptul că abuzul de nicotină şi alcool sunt cel mai frecvent întâlnite, apoi hipertensiunea arterială, agregabilitatea plachetară, dislipidemia (trigliceridele mărite), graviditatea, folosirea contraceptivelor orale, traumatismele cranio-cerebrale, encefalitele şi diabetul zaharat.

Identificarea factorilor de risc este un mijloc de scădere a riscului de boli cerebro-vasculare, prin reducerea factorilor de risc modificabili şi printr-o atitudine terapeutică mai adecvată datorită determinării cu acurateţe mai mare a stării de risc global.

În prezent în SUA există 4 milioane de oameni care au avut un accident vascular cerebral, iar în România există aproximativ 600.000 de bolnavi ce au suferit un accident vascular cerebral. Chiar şi după aceste cifre se impune pertinent identificarea factorilor de risc pentru accidentele vasculare cerebrale şi educarea comunitară privind accidentele vasculare cerebrale în vederea :

- reducerii impactului acestora;
- selectarea pacienţilor cu risc crescut la nivelul asistenţei primare;
- stabilirea unor scheme eficiente de profilaxie ce duc la scăderea incidenţei accidentelor vasculare cerebrale.

Psihologia omului contemporan în raport cu relaţia om sănătos - om bolnav este foarte complexă. Unii au o stare de linişte în legătură cu starea lor de sănătate, nesesizând nici o modificare notabilă, omiţând că în timp, firesc, organismul se uzează. Abuzul de alimente, stresul, sedentarismul, factorii ereditari predispozanţi, unele vicii, etc. predispun la tulburări care la început sunt imperceptibile clinic.

Încrederea în capacităţile ştiinţei medicale de a ne edifica asupra posibilităţilor reale ale organismului, dublată de o voinţă fermă de a acţiona conştient asupra vieţii noastre, ne poate face capabili să adoptăm o atitudine activă în menţinerea sănătăţii şi păstrarea cât mai îndelung posibil a acesteia. Aşa s-a născut şi s-a dezvoltat treptat acea concepţie nouă a medicinii denumită sanogeneză, care cuprinde totalitatea mijloacelor şi măsurilor pentru promovarea sănătăţii populaţiei.

Sănătatea şi boala reprezintă două concepte ce nu pot fi definite decât simultan, iar OMS a definit sănătatea ca fiind nu numai un concept negativ, adică absenţa bolii ci şi o stare completă de bine moral şi fizic. Există şi subiecte ce beneficiază de o „sănătate terapeutică” (ex. Sănătatea „insuliniană” a diabeticilor trataţi), pentru că se îngrijesc şi pentru atât timp cât se îngrijesc.

Depistările medicale prin acţiunile de control şi recontrol clinic şi paraclinic contribuie la depistarea bolnavilor necunoscuţi (ex. Controlul medical anual în organismele militare MAp, MI, SRI, CFR, Conel, etc.).

Trebuie subliniat faptul extrem de important, că în faţa bolii nu se poate face aproape nimic, dacă nu există o disciplină comportamentală şi terapeutică a bolnavului. În toate acţiunile întreprinse în scop profilactic (lupta împotriva fumatului, alcoolismului, sedentarismului, stress-ului, alimentaţiei neraţionale, obezităţii) aliatul de bază al medicului este omul, fiindcă el este responsabil şi beneficiar al stării proprii de sănătate şi al sănătăţii celorlalţi. Deci, acestui om trebuie să-i oferim surse de informare şi documentaţie pentru a înţelege care sunt adevăraţii săi duşmani care pot să-i decimeze sănătatea şi pentru a conştientiza aceşti factori pentru a lua o atitudine.

Prevenirea (profilaxia) înseamnă „ansamblul măsurilor care permit să se evite apariţia, apărarea şi extinderea unor boli” (definiţia OMS) şi ea se poate împărţi în mod schematic în prevenire: primară, secundară, terţiară.

Populaţia trebuie informată, sfătuită sau educată pentru a deveni cooperantă. Educaţia sanitară trebuie să înceapă de timpuriu, din perioada de şcoală şi să se desfăşoare fără discontinuităţi la locul său de muncă, în universitate, armată, spitale, cabinete medicale ambulatorii etc.

Medicii trebuie să înveţe şi să abordeze cu seriozitate problemele de depistare a factorilor de risc în diferitele boli, de evaluare a liniei evolutive, a traiectoriei patologice, să transforme relaţia medic-pacient, încât să înveţe să se exprime într-un limbaj comprehensibil pentru fiecare om, indiferent de gradul său de instruire, pentru stabilirea importanţei şi ierarhizarea factorilor de risc alcătuind chiar un „ profil de risc” pentru pacienţii săi.

Pentru clinician epidemiologia bolilor cerebro-vasculare oferă informaţii preţioase privind cunoaşterea frecvenţei diverselor tipuri de afecţiuni, în raport cu distribuţia lor geografică, naţională sau zonală şi a schimbărilor survenite în ultimul timp în patern-urile principalelor entităţi clinice.

Cercetările epidemiologice ale bolilor cerebro-vasculare au apărut în urma celor cardiace, cu toate că diagnosticul bolilor cerebro-vasculare este mult mai vechi din punct de vedere istoric. În acest sens de mare importanţă este evaluarea prognostică a factorilor potenţiali de risc, pe care îi prezintă orice bolnav în raport cu vârsta, sexul, tipul de afecţiune, încărcarea genetică, condiţiile de muncă şi viaţă, etc.

Pentru asigurarea unui sistem unitar de profilaxie, diagnosticare, tratament şi recuperare a bolnavilor cerebro-vasculari se impune cunoaşterea evoluţiei morbidităţii şi prevalenţei bolilor cerebro-vasculare, combaterea principalilor factori de risc din mediul de muncă şi viaţă, cât şi utilizarea cu randament corespunzător a bazei tehnico-materiale din dotarea unităţilor sanitare.

Profilaxia primară şi accidentele vasculare cerebrale se referă la depistarea precoce a factorilor de risc, la limitarea acţiunii unui factor de risc (ex. fumatul, obezitatea, sedentarismul etc.), care, deşi nu au un risc crescut de producere a accidentelor vasculare cerebrale decât numai în asociere cu alţi factori, sunt totuşi tratabili şi la dispensarizarea unor afecţiuni ce reprezintă factori de risc majori (hipertensiunea arterială, diabetul zaharat, bolile cardio-vasculare, bolile cu hematocrit crescut etc.). Tratamentul acestor afecţiuni poate contribui într-o măsură variabilă la reducerea incidenţei accidentelor vasculare cerebrale.

Există şi factori de risc recunoscuţi care nu pot să fie influenţaţi, cum ar fi spre exemplu: vârsta cronologică. Dintre factorii de risc majori cel mai important rămâne hipertensiunea arterială sistolică şi diastolică pentru toate decadele de vârstă care trebuie să fie corect susţinut şi permanent tratat.

Suntem în mileniul III şi se impune formarea unui nivel de cultură sanitară a populaţiei, indiferent de vârstă, statut socio-profesional şi cultural, pentru a stimula, prin cunoaştere gradul de cooperare în domeniul sanitar, fiind o garanţie a menţinerii şi promovării propriei sănătăţi la nivelul tuturor generaţiilor şi la cei ce ne vor urma (factorul de risc genetic-familial). O viaţă cumpătată în tinereţe, fără excese („a uza nu a abuza", „nici prea mult , nici prea puţin", „nici prea des, nici prea rar") cu o bătrâneţe activă şi frumoasă, poate să facă din fiecare om un longeviv care să fie util familiei, societăţii şi nu o povară sau factor perturbator în familie („ne naştem prin durere şi suferinţă, suntem investiţi cu speranţe şi perenitate de cei ce ne-au dat viaţă, ne dezvoltăm fizic şi psihic, ajungem la un apogeu-culme, apoi treptat coborâm panta spre ireversibilul firesc uman; depinde de noi, de medici şi societate ca această pantă să fie lină, suportabilă, lungă, fără obstacole şi prăbuşiri spectaculoase, cu o calitate a vieţii mulţumitoare").

CONCLUZII

1. Conţinutul noţiunii de „factori de risc" prezintă diferenţe faţă de cea de „factor etiologic" (factor cauzal). Numai o parte din factorii de risc se suprapun peste factorii etiologici;
2. Unii factori de risc nu presupun în mod necesar relaţii cauzale, ci favorizează alţi factori de risc în apariţia bolilor cerebro-vasculare;
3. Este important de amintit că prezenţa factorilor de risc nu implică în mod absolut o relaţie de cauzalitate directă, dar pot fi implicaţi în producerea bolii sau pot fi doar un marker nespecific al procesului patologic;
4. Identificarea factorilor de risc este un mijloc de scădere a riscului de boală cerebro-vasculară prin reducerea factorilor de risc modificabili şi printr-o atitudine terapeutică mai adecvată datorată determinării cu acurateţe mai mare a stării de risc global;
5. Reducerea factorilor de risc reprezintă abordarea clinică principală în prevenirea mortalităţii şi morbidităţii prin boli cerebro-vasculare;
6. Profilaxia multifactorială adresată simultan asupra unor combinaţii de factori de risc, întrerupând lanţurile de coincidenţe ce duc la boli cerebro-vasculare poate întârzia sau împiedica apariţia fenomenelor patologice;
7. Prevenirea primară a bolilor cerebro-vasculare este posibilă prin: controlul hipertensiunii arteriale (dispensarizare), scăderea concentraţiei colesterolului seric, combaterea fumatului, controlul diabetului zaharat, întrucât se însoţeşte de hipercolesterolemie;
8. A preveni este mai economicos şi mai eficient decât a trata.

Proteina C Reactiva şi glaucomul

Dr. Diana MELINTE[*]**, Lt.Col. Dr. C. ŞTEFAN**[*]
Mr. Dr. A. NENCIU[*]

SCOP: Evidențierea posibilelor implicații ale proteinei C reactive (PCR) în mecanismele etiopatogenice ale glaucomului.
MATERIAL SI METODĂ: Studiu clinic prospectiv, observțional pe doua loturi de pacienți: lot A (14 pacienți) cu glaucom si lotul B (12 pacienți) fără istoric de boli oculare sau alte boli generale cunoscute ca fiind asociate cu nivele plasmatice crescute ale PCR – lot martor. Loturile au fost omogene privind distribuția pe grupe de vârsta şi sex la includerea in studiu. Nivelul PCR a fost determinat cu teste de înaltă specificitate.
REZULTATE: Din analiza nivelelor serice ale PRC pe cele doua loturi de pacienți s-au observat diferențe statistic semnificative (p<0,0001) in cazul pacienților cu glaucom comparativ cu lotul martor: 3,87±0,8mg/dl in lotul A, respectiv 0,68±0,13mg/dl in lotul martor.
CONCLUZII: Glaucomul se asociază cu nivele serice crescute ale PCR. În etiopatogenia multifactorială a acestei boli, in care factorul vascular are rolul său bine stabilit, modificările inflamatorii vasculare pot reprezenta o componentă importantă.

glaucomul proteina C reactivă etiopatogenie

ABSTRACT
Purpose: To observe the possible implications of the C reactive protein in pathogenesis of the glaucoma
Methods: A clinical observational prospective study on 2 groups: group A 14 glaucomatous patients and group B - control (12 normal subjects) without history of ocular pathology or general pathology known to be associated with high plasma levels of CRP. The groups were homogeneous about the age and sex distribution. CRP levels were evaluated by tests with high specificity.
Results: The plasma CRP level reveals important differences (p<0,0001) on the two groups: 3,87±0,8mg/dl in the group A and 0,68±0,13mg/dl in the control group.
Conclusions: Glaucoma is associated with high plasma levels of CRP. In the complex pathogenesis of glaucoma, in witch the vascular factor has his well known place, the inflammatory vascular modifications may represent an important component.
Key words: the glaucoma; CPR; pathogenesis.

Răspunsul inflamator acut apare în urma unei agresiuni exterioare, fiind produs de o serie de factori: infecţioşi, non-infecţioşi, chimici, fizici sau toxici. Acest răspuns inflamator se însoțeşte de prezenta serica a reactanților de fază acută dintre care cei mai importanți sunt proteina C reactiva (PCR), haptoglobina şi fibrinogenul. Reactanții de fază acută sunt modulați prin intermediul citokinelor. Interleukina-1 (IL1), interleukina-6 (IL6) şi factorul de necroză tumorală (TNF) sunt principalii stimulatori ai sintezei hepatice ai reactanților de fază acută.

Proteina C reactiva (PCR) este cel mai sensibil reactant de fază acută, fiind o proteină din clasa pentaxinelor; alcătuită din 5 subunități polipeptidice identice care se prezintă ca pentameri ciclici. Fiecare subunitate are un situs de legare pentru fosfocolină şi doua situsuri de legare pentru calciu. (vezi fig. 1)

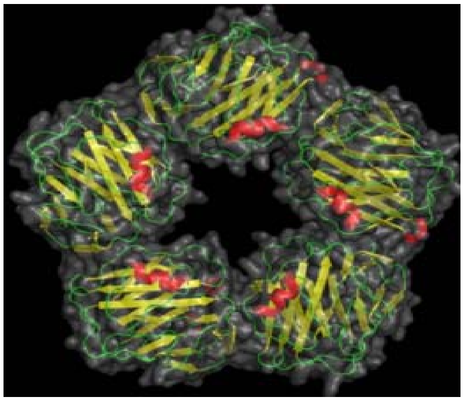

Fig.1. Proteina C reactiva

Patologia inflamatorie este incriminată într-o serie de afecţiuni generale precum ateroscleroza, boala Altzheimer sau boala Parkinson.

Multe studii recente arată asocierea între nivelele crescute ale markerilor inflamatori şi riscul de a dezvolta o patologie aterosclerotică chiar la pacienţii cu nivele bune ale colesterolului seric. În plus nivelele markerilor inflamatori, ai proteinei C reactive în particular , se asociază cu riscul de a dezvolta un episod recurent coronar la pacienţii cunoscuţi deja cu boala aterosclerotică cardiovasculară.

PCR reprezintă şi un marker important pentru sindromul metabolic, care la rândul lui influenţează prognosticul afecţiunilor cardiovasculare.

Actual exista 3 metode de a determina nivelul plasmatic al PCR: calitativ, semicantitativ şi cantitativ. Cel mai modern se folosesc testele cantitative, care sunt de înaltă sensitivitate: hs-CRP (''high sensitivity'' CRP test).

În ultima vreme se vorbeşte tot mai mult de rolul inflamaţiei într-o serie de afecţiuni, din care nici patologia ofatalmologică nu face excepţie. Patologia glaucomatoasă se caracterizează printr-o etiologie multifactorială, în care rolul inflamaţiei îşi pune amprenta.

În urma studiilor recente s-a demonstrat că diverse gene cu rol în codificarea proteinelor implicate în procese inflamatorii precum: chemochinele ligand 5/6, nucleotide imun asociate, receptorul pentru IL1, transtiretina sau haptoglobina se asociază cu glaucomul.

Întregul proces inflamator este întreţinut de expresia moleculelor inflamatorii la nivel tisular, care rezultă pe seama radicalilor liberi de oxigen, aceştia iniţiind şi contribuind la progresia leziunilor glaucomatoase.

Stressul oxidativ, mediat tot de radicalii liberi de oxigen produce leziuni pe moleculele ADN-ului celular din reţeaua trabeculară şi din celulele ganglionare retiniene, care în final conduc la progresia glaucomului.

Studii recente implică disfuncţiile endoteliale secundare scăderii biovalabilităţii oxidului de azot, prin creşterea stressului oxidativ, în acumularea de proteină C reactiva, cu acelaşi rezultat final – progresia leziunilor glaucomatoase. (vezi graficul nr.1)

PROGRESIA GLAUCOMULUI

Grafic 1. Inflamația în glaucom

Pornind de la aceste premise scopul lucrării noastre este de a observa implicarea proteinei C reactive (PCR) în etiopatogenia si evoluția glaucomului.

Am realizat un studiu clinic prospectiv, observațional cu durata de un an, pe două loturi de pacienți:
- lotul A: alcătuit din 14 pacienți diagnosticați cu glaucom primitiv cu unghi deschis şi glaucom normotensiv, în acelaşi stadiu de evoluție;
- lotul B: lot martor, alcătuit din 12 subiecți clinic sănătoşi.

Criteriul de excludere, valabil pentru ambele loturi, a fost asocierea oricărei patologii oculare sau generale inflamatorii.

Evaluarea nivelelor plasmatice ale PCR a fost realizată cu teste de înaltă sensibilitate bazate pe principiul ELISA. Pentru fiecare pacient al fiecărui lot în parte au fost realizate câte trei determinări ale PCR: la includerea în studiu, la 6 luni şi la 12 luni.

Prelucrarea rezultatelor s-a realizat prin analiză statistică cu ajutorul testului Mann Whitney şi coeficientului de coreleție Spearmann.

Cele doua loturi au fost omogene privind distribuția pe vârstă si sex. Lotul A s-a alcătuit din două subgrupe: 9 pacienți cu glaucom primitiv cu unghi deschis şi 5 pacienți cu glaucom normotensiv. In tabelul 1 se observă ca raportul bărbați/femei şi media de vârsta a fost echivalent pentru ambele loturi.

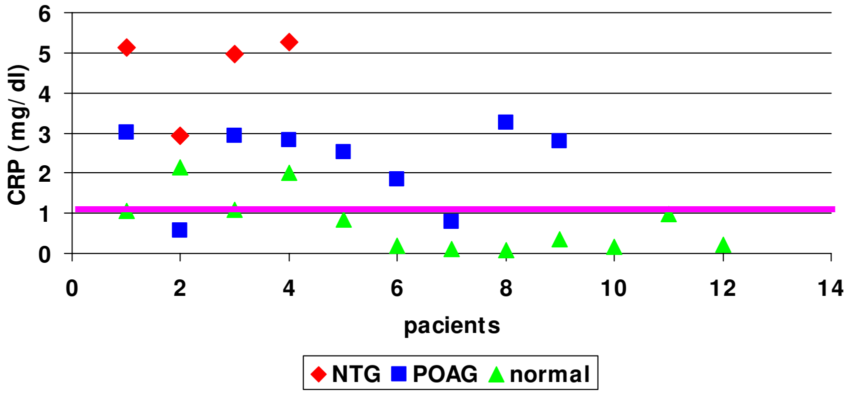
Distributia dupa varsta si sex

	Group A				*Group B*	
	POAG		*NTG*		*normal*	
	M	*F*	*M*	*F*	*M*	*F*
	5	*4*	*2*	*3*	*7*	*5*
Age (years)	*69±4*	*67±6*	*72±5*	*70±3*	*68±7*	*73±5*

Tabel 1. Distribuţia pe vârste şi sex

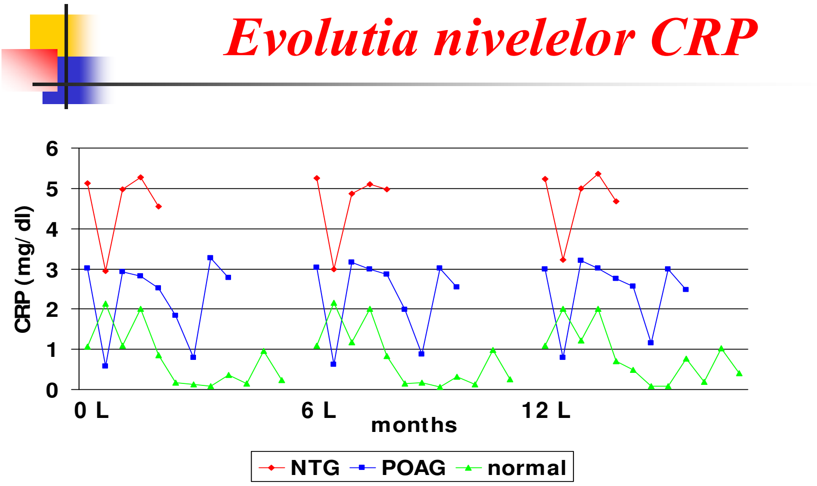
Prima determinare a PCR de la începutul studiului a evidenţiat că in cadrul lotului martor peste 80% din subiecţi au prezentat valori plasmatice în limite normale: adică sub 1mg/dl. In lotul A 77% din pacienţii cu glaucom primitiv cu unghi deschis au valori ale PCR peste nivelul normal admis; iar pacienţii cu glaucom normotensiv în proporţie de 100% prezintă valori ridicate plasmatice. (vezi graficul 2)

CRP-prima evaluare



Grafic 2. PCR – prima determinare

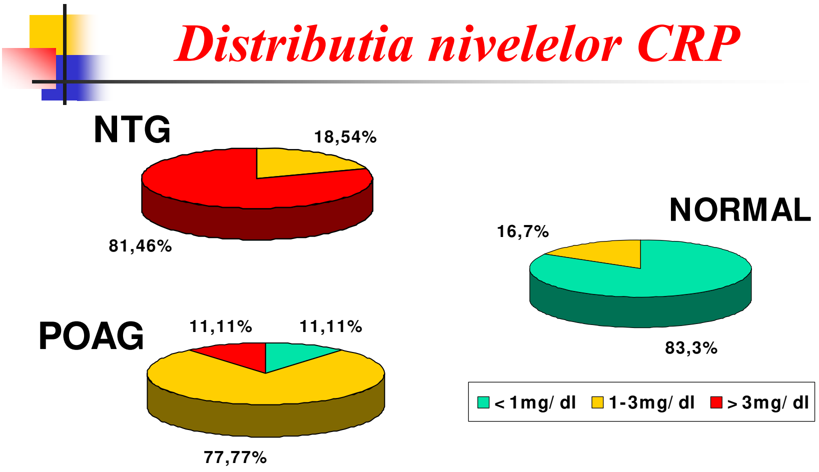
Urmărind în dinamică evoluţia nivelelor plasmatice ale PCR se observă că atât la 6 luni, cât şi la 12 luni se menţin aproximativ aceleaşi valori ca la prima determinare, cu minime variaţii.(vezi graficul 3)



Grafic 3. Evoluţia PCR

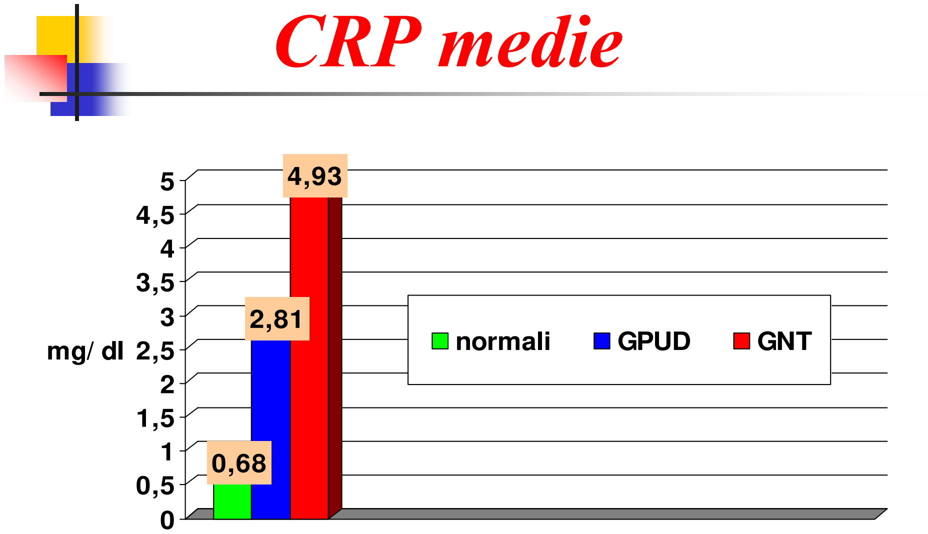
În ceea ce priveşte distribuţia pe nivele a PCR pe loturi se observă că peste 80% din pacienţii clinic normali prezintă valori în limite normale (sub 1mg/dl), în timp ce doar 11% din pacienţii cu glaucom primitiv cu unghi deschis se găsesc în acest interval. Restul de aproximativ 77% au valori ale PCR moderat ridicate: între 1 şi 3mg/dl.

Cel mai spectaculos se prezintă lotul pacienţilor cu glaucom normotensiv la care peste 80% din pacienţi prezintă valori mult crescute ale PCR: peste 3mg/dl. (vezi graficul 4)



Grafic 4. Distribuţia pe nivele a PCR

Analizând media nivelelor proteinei C reactive se observă că subiecții lotului martor au o medie în limite normale (0,68mg/dl), pacienții cu glaucom primitiv cu unghi deschis au o medie moderat crescută (2,98mg/dl); în timp ce pacienții cu glaucom normotensiv prezintă nivelul cel mai ridicat de 4,93mg/dl. (vezi graficul 5)



Grafic 5. Media nivelelor PCR

Studiul de față demonstrează faptul că nivele ridicate ale proteinei C reactive se asociază cu patologia glaucomatoasă. Se demonstrează o implicare mai activă a proteinei C reactive în patologia glaucomului normotensiv prin valori plasmatice mult mai mari fața de glaucomul primitiv cu unghi deschis.

Creşterea nivelelor serice ale proteinei C reactive este implicată direct în progresia leziunilor glaucomatoase.

Factorul vascular incriminat în glaucom, dar şi în alte patologii generale precum ateroscleroza, boala Altzheimer, boala Parkinson este amplificat de factorul inflamator.

Prin aceste descoperiri se doreşte deschiderea unor noi orizonturi de abordare terapeutică a bolii glaucomatoase.

Iridociclita acută psoriazică

Lt.Col.Dr. Cornel STEFAN[*] Dr. Anna SAPUNDGIEVA*
Cpt. Dr. Adrian NENCIU[**] Dr. Diana MELINTE*

Rezumat: Prezentăm cazul unui ofițer de 33 ani, diagnosticat cu psoriasis in urmă cu 12 ani, care se prezintă în clinica de oftalmologie a S.C.U.M.C. cu iridociclita acută. Evoluția sub tratament a fost favorabilă, cu recuperarea funcțională completă. Considerăm apariția iridociclitei ca fiind un semn unic şi tardiv a bolii sistemice.

psoriazis iridociclita acută tratament recuperare

Abstract: We present the case of an officer, 33 years old, with anterior uveitis. The patient was diagnosed with psoriasis 12 years ago. With treatment the evolution was favorable and the recovery was complete. We consider that the apparition of anterior uveitis is an unique and late sign of the systemic disease.

Key words: Psoriasis, Anterior uveitis

Vă prezentăm cazul pacientului S.I., ofițer, 33 ani, sex masculin, cu domiciliu în Bucureşti, care se internează în clinica de oftalmologie a Spitalului Militar Central pe 26.02.2007, acuzând OS: dureri oculare, vedere încețoşată, fotofobie, lăcrimare, prim episod de ochi roşu. Din antecedentele personale patologice reținem - psoriazis vulgar, forma uşoară, diagnosticat in 1995, în tratament local cu Calcipotriol (Daivonex).

Istoricul bolii

Debutul suferinței oculare a fost în urma cu 3 zile, motiv pentru care pacientul s-a prezentat initial într-o altă clinica de specialitate. În momentul examinării în clinica noastră el a fost sub tratament local OS: cicloplegic (Mydriacyl 0.5%), timolol (Arutimol). Subconjunctival i s-a injectat Diprophos. Tratamentul general – Ederen, Voltaren retard.

În urma tratamentului menționat simptomatologia subiectivă nu se ameliorează si urmează prezentarea pacientului în clinica de oftalmologie a S.C.U.M.C.

Rezultatele examinărilor clinice obiective generale efectuate de noi constată prezența modificărilor active date de psoriazis doar la nivelul coatelor(eritem, scuame)(**Figura 1**)

---

Figura 1: Modificările date de psoriazis la nivelul coatelor

Examenul oftalmolofic obligatoriu decelează:
VOD=1 cc – 0,75 D cyl ax 170°
VOS=1fc, cd (vedere încețoşată)
TOD=19 mmHg Goldmann
TOS=12 mmHg Goldmann
AO: percepție si proiecție de lumină în toate cadranele
Aspectul biomicroscopic al polului anterior*:*
OD: Aspect normal (**Figura 2**); OS(**Figura 3**)

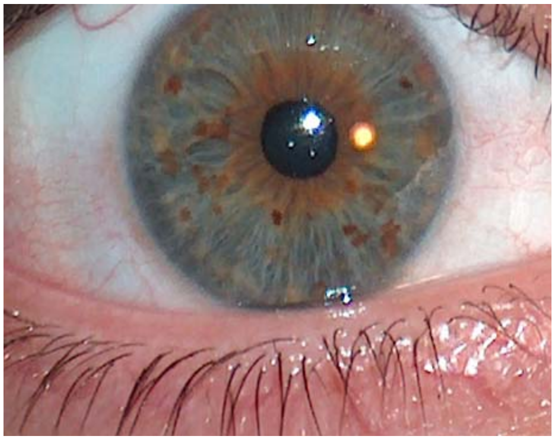

Figura 2: Examen pol anterior ochi drept

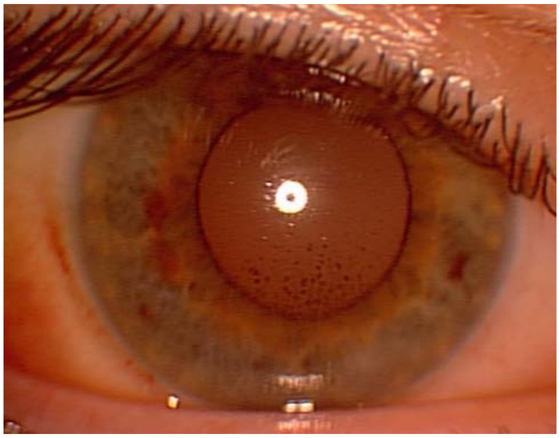

Figura 3: Examen pol anterior ochi stâng

- Conjunctiva – ochi roşu , fără secreții patologic
- Cornee – precipitate keratice endoteliale rotunde, nepigmentate, în ⅓ inferioară – medie a corneei.
- CA – de profunzime medie, Umor apos cu discret Tyndall
- Iris – desen stromal normal, guleras pigmentar integru
- Pupila – rotunda, centrala, semimidriaza fixă
- Cristalin – transparent

Examenul **fundului de ochi** la AO este fără modificări patologice (**Figura 4**)

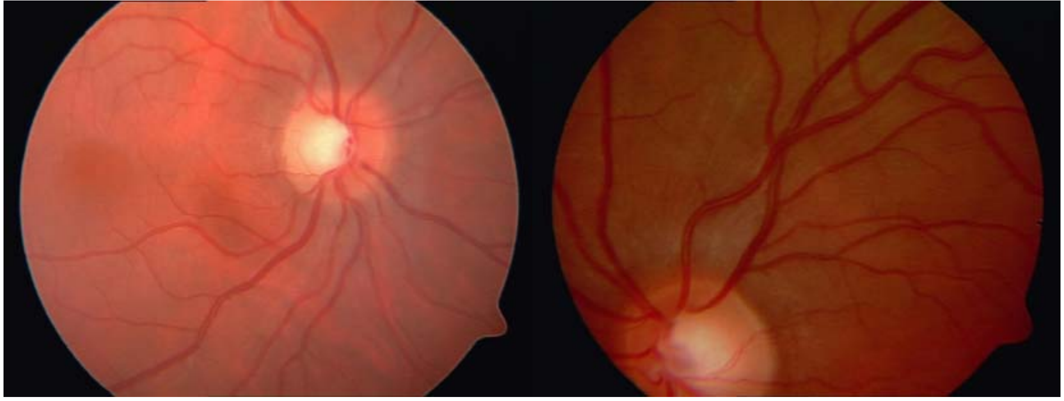

Figura 4 : Examen fund de ochi – fără modificări patologice

Ecografia oculo – orbitara nu a evidențiat modificări patologice (**Figura 5**)

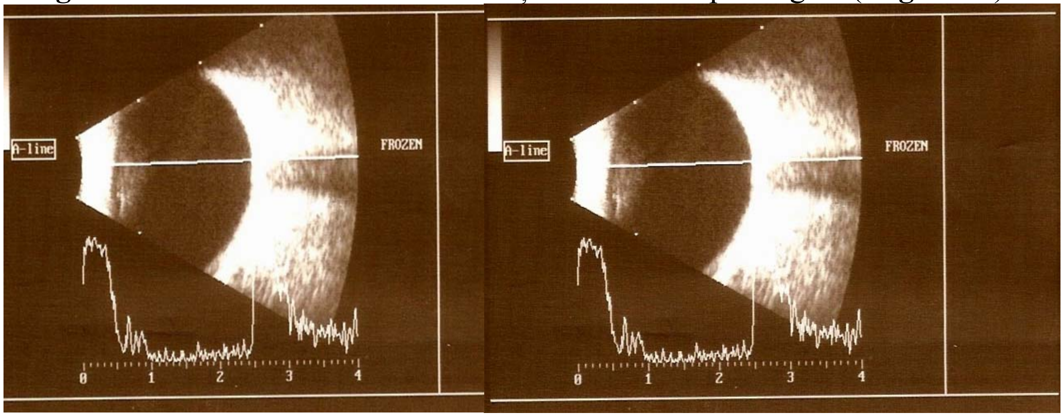

Figura 5: Ecografie oculoorbitară – fără modificări patologice

Pe baza anamnezei şi a examenului de specialitate ne-am orientat spre următorul **diagnostic de prezumție**:

- Psoriazis vulgar, forma uşoară
- OD: astigmatism miopic simplu
- OS: iridociclită acută

Pentru stabilirea diagnosticului pozitiv am solicitat: consult dermatologic(psoriazis vulgar, forma uşoară), ORL, reumatologic, urologic (in afara diagnosticului de psoriazis nu a fost diagnosticată nici o altă afecțiune) şi investigații de laborator cu următoarele rezultate:

VSH – normal
Proteina C reactivă, factor rheumatoid, VDRL, HIV – negative
HLG, glicemie - normal
Ac anti Chlamidia, Ac anti B.burgdorferi – absenți
HLA B27 – absent
Rx cardio – pulmonar, articulații sacro – iliace, craniu-fără modificări patologice
CT sinusuri anterioare si posterioare ale feței, articulații sacro – iliace – fără modificări
Sumar urina, urocultură, secreție uretrală – în limite normale
S – a stabilit următorul **diagnostic pozitiv**:
Psoriazis vulgar, forma uşoară
OD: astigmatism miopic simplu
OS: iridociclita acută psoriazică

S – a instituit tratament topic la OS si tratament general

Tratament topic - Midriatice (Mydriacyl)
- Corticosteroizi (Maxidex)
- Antibiotice (Tobradex)
- Antiinflamatorii nesteroidiene (Voltaren ophtha)

Tratament general - Antibiotic (Zinnat)
- Antihistaminic (Alerid)
- Vitamină C
- AINS (Voltaren 100 mg(retard), pansament gastric, 10 zile

În urmă eficienței deficitare a tratamentului (tradusă prin creşterea numărului de precipitate keratice), pacientului i s –a impus administrarea de Prednison per os 1 mg ⁄Kg corp o dată pe zi, cu scăderea treptată a dozei. Se externează cu ameliorarea simptomatologiei dar cu câteva precipitate corneene endoteliale restante. La primul control(10 zile după externare) nu se mai observă precipitate endoteliale (**Fig. 6, 7**).

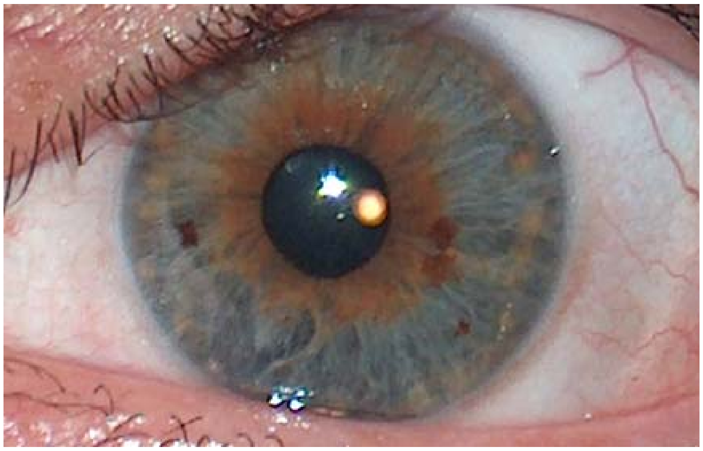

Figura 6: Evoluție ochi stâng sub tratament

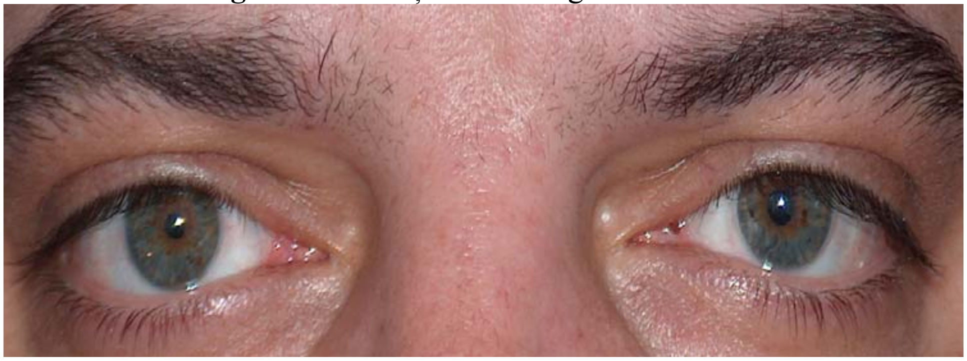

Figura 7: Evoluție după tratament

Particularitatea cazului şi concluzii

Iridociclita acută la un pacient cu psoriasis, dar fără artrită psoriazică, aflat la primul episode de ochi roşu şi care sub tratament are o evoluție net favorabilă cu recuperare funcțională de 100 %

Nu a avut repercusiuni medico–militare.

Predicția riscului de moarte subită cardiacă prin alternanța undei T

Dr. Nicolae RĂDOI[*]

REZUMAT

Alternanța undei T (AT), de ordinul microvoltilor, este o nouă metodă clinică pentru evaluarea riscului de Moarte Subită Cardiacă. Alternanța undei T este rezultatul alternanței in durata potențialului de acțiune al celulei miocardice. Mecanismele celulare ale alternanței sunt legate de curba de restituire si perturbările cineticii intracelulare a ionilor de calciu cu afectarea schimbului Na –Ca sarcolemal. Alternanța discordantă, în care două regiuni miocardice învecinate prezintă alternanță în opoziție de fază, creează substratul electrofiziologic al reintrării prin dispersia marcată a refractarității miocardice. Testul AT este pozitiv când alternanța este susținută pentru cel puțin 1 minut, cu un voltaj mai mare de 1,9 µV. Studiile clinice publicate prezintă AT ca pe un marker important al riscului de aritmii ventriculare.

alternanața undei T metoda clinică Moarte Subită cardiacă

ABSTRACT

The alternation of T wave (AT) is a new clinical method to evaluate the sudden heart death risk. The alternation of T wave is the result of this alternation during the action potential of the myocardic cell. The cell mechanisms of the alternation are linked to curve restoring and perturbations of the intracell kinetics of calcium ions, altering the Na-Ca sarcolemmal exchange. The discordant alternation where two neighbouring myocardic zones have an alternation in phase opposition creates the electro-physiological re-entering substrate through the pronounced dispersion of myocardic refractory. The AT test is positive when the alternation is sustained for at least one minute, with a voltage higher than 1.9 µV. The clinical studies which are already published show the AT as an important marker of ventricular arrhithmias risk.

INTRODUCERE

Moartea Subită Cardiacă (MSC) rămâne o problemă majoră de sănătate publica, chiar şi în țările dezvoltate economic, unde reprezintă 11% din totalul deceselor şi cca 50% din decesele cardiace. 80% din cazurile de MSC survin la pacienții cu boala aterosclerotică coronariana. Singurul mijloc terapeutic în profilaxia primară sau secundară a MSC este defibrilatorul cardioverter implantabil (ICD). Predicția adecvata a riscului de MSC este foarte importanta pentru profilaxia primara, cost eficienta a MSC prin implant de ICD. Prețul mare al aparatului impune o selecție riguroasă a pacienților. Stimularea ventriculara programata (SVP), mult controversata in literatura de specialitate este invazivă şi costisitoare. Markerii noninvazivi clasici de risc aritmic, au specificitate şi valoare predictivă pozitivă mică.

Doar doi parametri noninvazivi se asociază semnificativ statistic cu riscul de MSC pentru luarea deciziei de a implanta profilactic un ICD. Aceştia sunt fracția de ejecție a ventriculului stâng (FEVS) şi alternanța undei T (AT) pe electrocardiograma. În SUA, metoda AT a primit aprobarea „Food And Drug Admnistration” (FDA), în anul 2000, pentru evaluarea riscului de MSC.

Detecția AT de ordinul microvolților pe ECG este asociată unui risc crescut de fibrilație ventriculară primară. În funcție de substratul anatomopatologic şi entitatea clinică, valoarea predictivă pozitivă pentru riscul de MSC se situează între 25 - 70%.

---

[*] Spitalul Militar de Urgență Timişoara Secția Cardiologie

ISTORIC

Alternanța undei T este alternanța electrică în care morfologia undei T se modifică de la o bătaie la alta într-o succesiune de tip ABABAB…..Primele observații despre AT aparțin lui Hering, în anul 1908[1]. În 1913, Windle[1] descrie pulsus alternans la pacienții cu cardiomiopatie severă şi conchide că "alternanța adaugă totdeauna la gravitatea prognosticului". În anul 1988, Smith, introduce în studiul AT metoda de analiză spectrală[2] care permite detectarea alternanței electrice de ordinul μV. În 1997 a fost publicat primul studiu în care determinarea AT s-a făcut prin test de efort ECG [3].

BAZELE ELECTROFIZIOLOGICE ALE AT

Studii de mapping optic au demonstrat că mecanismul care generează apariția AT este alternanța localizată în durata potențialului de acțiune (DPA). Conform ipotezei restituirii alternanța DPA apare atunci când înclinarea curbei de restituire (DPA exprimată în funcție de intervalul diastolic precedent) este mai mare decât 1 la valoarea curentă a intervalului diastolic[4]. Alternanța localizată a DPA se reflectă pe ECG în AT. Studiile de mapping optic ale lui Pastore şi Rosenbaum au evidențiat că AT pe ecg de suprafață este sincronă cu alternanța DPA[5].

MECANISMELE PRINCIPALE CELULARE ŞI SUBCELULARE

Se accepta trei mecanisme principale:

1. O panta > 1 a curbei de restituire, expresia relației intre DPA si intervalul diastolic anterior. Curba de restituire este dependenta de kinetica curenților repolarizării membranei celulare. Analiza stabilității DPA în contextul unor creşteri bruşte ale frecvenței cardiace impune folosirea curbei restituirii dinamice. Simulări computerizate ale efectelor schimbărilor de ritm cardiac asupra secvențialității DPA, prin folosirea curbelor de restituire dinamice obținute experimental au arătat că, reproducerea cu acuratețe a succesiunii DPA, necesită, de asemenea, includerea efectelor pe termen scurt ale memoriei cardiace, respectiv dependența DPA de durata PA şi intervalelor diastolice premergătoare. Pentru aceasta, Kalb[6] a recomandat folosirea „portretului restituirii" care cuprinde atât restituirea dinamică cât şi pe cea statică. Exista însă, forme de alternanță, ca de exemplu alternanța ischemică, în care înclinarea curbei restituirii este < 1.

2. Perturbarea reciclării intracelulare a ionilor de Ca, cu alternanță secundară a DPA prin afectarea princeps a schimbului Na-Ca. Studiile de mapping optic au arătat că alternanța spațială a calciului citosolic se corelează cu alternanța DPA. Perturbarea reciclării intracelulare a ionilor de Ca se poate realiza prin disfuncția receptorului pentru rianodina, Ca-ATP-azei reticulului sarcoplasmatic (SERCA) sau schimbului Na/Ca. Heterogenitatea spațială a alternanței calciului intracelular se corelează cu dispersia DPA în timpul AT. Diferențele de exprimare a SERCA 2a şi receptorului pentru rianodina pot constitui baza moleculara a diferențelor regionale în susceptibilitatea la alternanță[7].

Fluctuațiile Ca citosolic pot afecta secundar repolarizarea membranei prin intermediul curenților de membrana Ca – sensibili.

3. Alternanța în velocitatea conducerii miocardice prin modificările primare ale curbei de restituire ale vitezei de conducere miocardice. Acest mecanism poate fi legat de remodelarea primară a conexinelor miocardice.

ALTERNANȚA DISCORDANTA - mecanismul aritmogen

Alternanța în DPA nu este un proces cu distribuție uniformă în miocard. La fel cum DPA şi restituirea sunt distribuite ca şi gradienți de la apex la bază şi de la epicard la endocard, la fel sunt reprezentate magnitudinea şi faza alternanței la o anumită frecvența cardiacă (FC).

Potențialul de acțiune la baza ventriculului poate alterna în succesiunea lung – scurt - lung, iar la vârful ventriculului, simultan, alternanța să aibă succesiunea scurt – lung - scurt.

Pastore şi Rosenbaum[5] au folosit pentru descrierea acestui tip de alternanță, termenul de alternanță spațial discordantă (AD). În modelul experimental descris de Rosenbaum[5], prezența AD a fost condiția obligatorie pentru inițierea aritmiilor ventriculare.

Regiunile cu alternanță opusă sunt separate de zone de alternanță zero, cunoscute ca "noduri", care tind să fie orientate în direcția bază-apex. Odată cu depărtarea de zonele nodale magnitudinea alternanței creşte. Pot fi implicate in dezvoltarea alternantei discordante fluctuațiile calciului intracelular sau restituirea bifazica. Fox propune însumarea a trei factori pentru apariția AD şi instalarea blocului conductiv: prezența interacțiunilor electrotonice intercelulare; existenta unei funcții de recuperare a velocitatii conducerii; curba de restituire >1. In cadrul simulărilor sale computerizate, heterogenitatea restituirii este creată prin combinația dintre alternanta velocității conducerii şi curba abruptă a restituirii[6].

FACTORI MODULATORI AI ALTERNANȚEI

Ischemia, frecvența cardiacă şi nivelul tonusului simpatic sunt principalii factori care pot modula AT. Alternanța DPA poate fi privită ca o proprietate intrinsecă a miocardului ischemic[8]. Evaluarea riscului aritmic intrinsec prin AT se va face numai după excluderea ischemiei miocardice. Este însă foarte important de subliniat faptul că nu există dovezi că AT asociată unui risc crescut de aritmii ventriculare la om, ar fi în vreun fel dependentă de prezența ischemiei miocardice[8].

În general, o creştere de tonus simpatic determină o creştere a magnitudinii AT. Administrarea de beta-blocante scade nivelul de alternanță. Există opinii divergente în ceea ce priveşte necesitatea întreruperii beta-blocantelor înaintea efectuării testului. Recomandarea centrelor cu experiență este ca testul să se desfăşoare cu bolnavul sub medicația curentă.

Alternanța T este dependentă de FC. Chiar şi persoane fără afectare cardiacă pot prezenta AT semnificativă la FC mari, de obicei peste 120/min. S-a arătat că FC de debut a AT este mai redusă la pacienți cu afectare structurală cardiacă şi antecedente de aritmii ventriculare susținute, decât cei fără trecut cardiac sau antecedente aritmice. Rezultatele fals pozitive cresc la FC mai mari de 120/min. Condiția esențială pentru un test pozitiv este debutul AT susținute sub 110 bătăi/min.

INTERPRETARE, CLASIFICARE

În practica clinică, se foloseşte actualmente metoda analizei spectrale, dezvoltată de grupul de cercetători condus de Richard J Cohen de la M.I.T, Cambridge, USA. Pentru a calcula un spectru se utilizează 128 măsurători efectuate la nivelul punctelor corespunzătoare a 128 unde T consecutive. Frecvențele rezultate sunt exprimate în cicli/bătaie cardiacă (în loc de cicli/sec). Punctul din spectru, corespunzător la exact 0,5 cicli/bătaie indică nivelul de detecție al AT (Fig.1).

Acest colectiv a pus la punct tehnica necesară pentru evaluarea standardizată a AT prin proba de efort ecg obişnuită. Aparatura este comercializată sub denumirea "HEARTWAVE" şi este proprietatea firmei "CAMBRIDGE HEART". La noi în țară, de vânzarea aparatului, se ocupă firma "PHILIPS"(Fig.2)

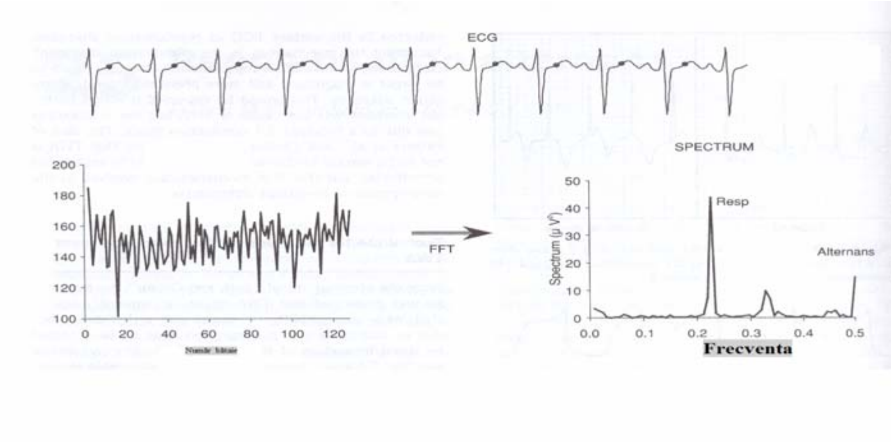

Figura 1 Transformarea Fourier a unei serii termporale pentru analiza spectrala a alternantei T

Rezultatele analizei sunt exprimate sub forma unor indici[9]:

- puterea alternanței(µV 2) : măsoară nivelul fiziologic real al AT;
- voltajul alternanței, exprimat în µV, reprezintă rădăcina pătrată a puterii alternanței;
- raportul alternanței, sau scorul K calculat ca raportul dintre puterea AT şi deviația standard a zgomotului în frecvența de referință. Alternanța T este considerată semnificativă dacă Indicele K este>3.

CLASIFICAREA TESTELOR de AT: Alternanța susținută: AT evident prezentă la frecvențe cardiace mai mari decât frecvența de debut; cu cel puțin 1 minut cu Valt >1,9 µV şi raport K >3 ; în oricare din derivațiile X, Y, Z sau VM (vector maxim) sau una din derivațiile precordiale, confirmată de o derivație precordială adiacentă (cu Valt>1,9µV). Alternanța poate fi considerată susținută chiar dacă magnitudinea scade la FC > 120/min[9].

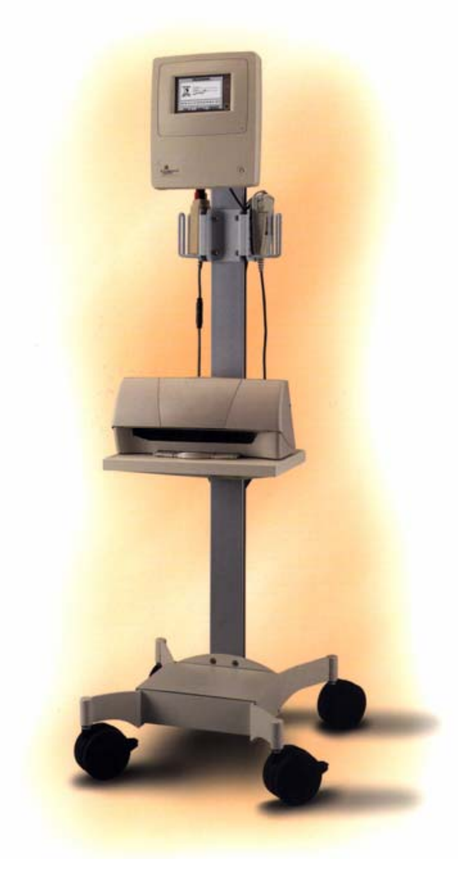

Figura 2 Aparatul "HEARTWAVE"

Criteriile de clasificare[9]: Test pozitiv (Fig. 3): AT susținută la o FC de debut (FCd) <110/min sau AT susținută la FC de repaus, chiar dacă aceasta este >110 b/min. Test negativ (Fig. 4): Regulile A: 1)Testul nu îndeplineşte criteriile pentru a fi pozitiv şi 2) frecvența cardiacă negativă maximă este >105b/min. Regulile B: testul este de asemenea clasificat ca negativ dacă pe timpul unui exercițiu maximal FC maximă este > 80 b/min şi dacă FC negativă maximă > (Fcmax - 5b/min). Test nedeterminat (echivoc): testul nu poate fi definitiv clasificat fie pozitiv, fie negativ.

Deoarece regulile B au fost testate clinic, prospectiv şi retrospectiv, Bloomfield[9] recomandă adoptarea lor în clinică, pe considerentul reducerii numărului de teste echivoce.

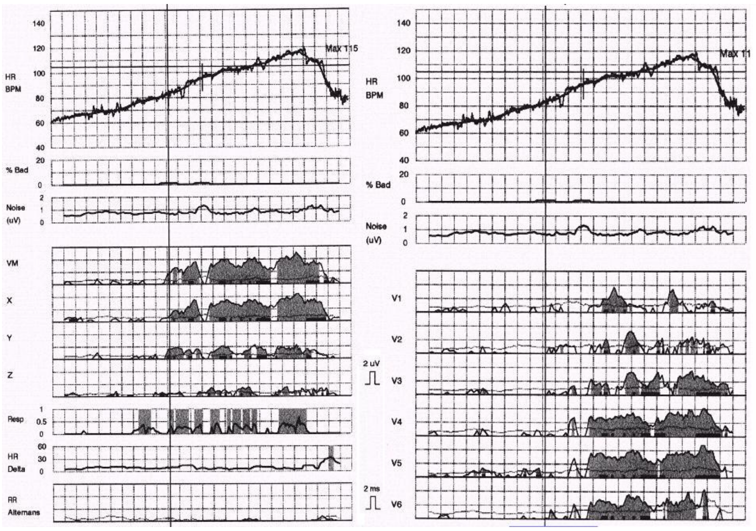

Figura 3. Test de AT pozitiv

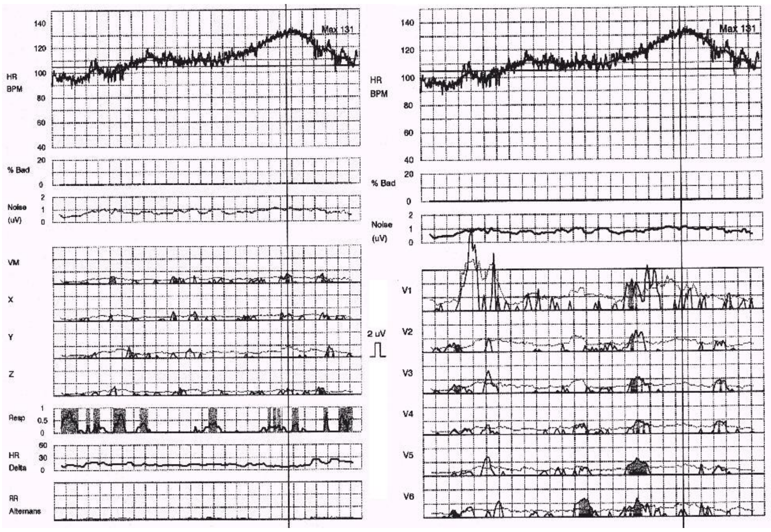

Figura 4. Test de AT negativ

Contraindicațiile pentru testarea AT sunt: fibrilația atrială, extrasistolia atrială frecventă, extrasistolia ventriculară, ritmurile electrostimulate ventriculare, reacțiile adverse la electrozii tegumentari. Reproductibilitatea pe termen scurt a metodei este satisfăcătoare. Turitto[10] compară înregistrările succesive de mAT efectuate la interval de 4 ore unul de altul. Din 42 de pacienți cu 2 înregistrări succesive, 39(93%) au prezentat rezultate concordante.

PRINCIPALELE REZULTATE CLINICE

Pacienți cu risc de aritmii ventriculare maligne (Tahicardie Ventriculară, TV, Fibrilație ventriculară, FV). Rosenbaum a publicat, în 1994, primul studiu clinic[11]: 83 de pacienți la care s-a determinat AT prin stimulare atrială concomitent cu SVP. La 32 pacienți cu SVP pozitivă, AT a fost un predictor al inductibilității TV cu o sensibilitate de 81% şi o specificitate de 84%.

Ca valoare predictivă, AT a fost echivalentă SVP. Ulterior, mai multe studii clinice[12-15] au dovedit valoarea predictivă a AT pentru riscul de aritmii ventriculare. Relevant este faptul că, după studiul lui Gold[13], FDA a aprobat oficial AT pentru evaluarea riscului de MSC în SUA.

Pacienți cu disfuncție de VS.

Studii clinice recente[16-21] au arătat că AT poate fi folosită pentru evaluarea riscului aritmic la pacienții cu Insuficiență cardiacă congestivă şi Cardiomiopatie dilatativă. În insuficiența cardiacă, pacienții cu AT (+) au avut o mortalitate de 10% la 2 ani, față de numai 1% la grupul cu AT negativă[17]. Valoarea predictivă negativă excelentă a AT este deosebit de utilă clinic la pacienții de tip MADIT II : date recente relevă că la bolnavii postinfarct miocardic cu FE <30% şi AT (-) nu este necesar implantul profilactic de ICD.

Pacienți cu Sincopă.

Bloomfield[22], analizând rezultatele AT la pacienți coronarieni cu sincopă, ajunge la concluzia a fost că AT poate identifica cel puțin la fel de bine ca SVP un subgrup de pacienți cu risc mare de MSC sau aritmii ventriculare. Pacienții cu AT (-) au un prognostic excelent şi de cele mai multe ori nu ar mai necesita investigații suplimentare.

Marangoni[23] a sugerat că utilizarea AT ca test de screening la pacienții coronarieni cu sincopă ar putea reduce foarte mult costurile de spitalizare. Argumentele au fost următoarele: metoda AT are sensibilitatea şi specificitatea similare SVP dar este de 10 ori mai ieftină şi fără nici un risc pentru pacient. Datorită faptului că în toate trial-urile clinice (2000 pacienți) valoarea predictivă negativă este aproape 99% (aproape nici un pacient cu AT negativă nu a prezentat MSC în următoarele 15 luni), este justificată economic doar internarea pacienților cu test AT(+).

Pacienți cu Infarct miocardic.

La 850 bolnavi, cu IM în antecedente, Ikeda[23] găseşte AT cel mai bun predictor de risc aritmic: un test de AT pozitiv ar indica un risc de aproximativ 20% pentru apariția în următorii 2 ani de MSC, FV sau TV.

Implicațiile AT in selecția pacienților cu indicație de implant de ICD.

Deoarece testul AT este util pentru relevarea riscului de aritmii ventriculare, poate fi folosit ca test de screening pentru identificarea bolnavilor care să fie adresați SVP şi să beneficieze de implantul de ICD. Testul poate delimita pacienții cu risc minim, care nu necesită implant profilactic de ICD.

Ezekowitz[25] analizează eficacitatea implantului de ICD la persoane cu risc crescut de MS, subliniind că deciziile referitoare la alocarea resurselor pentru ICD depind de stratificarea cu acuratețe a pacienților în funcție de risc.

Autorii rezumă rezultatele a 8 trial-uri care au inclus 4909 pacienți: AVID, CASH, CIDS, MADIT, CABG patch, MUSTT, MADIT II, CAT. ICD a redus riscul relativ pentru MSC cu aproximativ 50%, independent de riscul bazal. Analiza efectuată relevă o mare variabilitate a raporturilor de cost eficiență cu valori între 17,700 şi 138,800 dolari pe an de viață salvată. Marea variabilitate în raporturile de cost eficiență relevă importanța unei stratificări cu acuratețe a riscului aritmic, în vederea determinării pacienților care să beneficieze maximal de tratamentul prin ICD.

CONCLUZII

Alternanța undei T este un test clinic neinvaziv indicat în practica cardiologică pentru analiza riscului de aritmii ventriculare şi de MSC. Valoarea predictivă pozitivă, după diversele studii existente este variabilă, de la 25% la 80%, în funcție de afecțiunea de bază.

În anumite situații clinice, valoarea predictivă pozitivă poate fi crescută prin corelarea AT cu rezultatele SVP. Valoarea predictivă negativă este mai mare de 99%. Testul AT poate fi folosit in screeningul riscului de MSC la grupele de risc cardiovascular.

Tulburarea de Stres Posttraumatic – o realitate a societății româneşti

Psiholog Principal Iuliana ZAVADOVSCHI[*]
Conf. Dr. Col. (r) Viorel ARMAŞU[*]

OBIECTIV: Importanța cercetării tulburării de stres posttraumatic (TSPT) pentru societatea românească ca urmare a creşterii numărului de militari şi angajați civili care au participat în diverse teatre de operațiuni şi manifestă simptome ale acestei tulburări psihice.
MATERIAL ŞI METODĂ: 3,2% din militarii care s-au întors din teatrele de război au fost diagnosticați şi au primit tratament pentru TPST; aproximativ 7% din cei care s-au reîntors şi nu au fost diagnosticați şi nu au solicitat consult psihiatric/psihologic de specialitate, având altă simptomatologie pentru care a fost solicitată evaluare psihologică, prezentau simptomele TSPT, motivând „ruşine" şi „frică" să recunoască starea lor în fața superiorilor. De asemenea am primit solicitări şi din partea familiilor pentru consiliere („nu reuşim să-l mai înțelegem", „s-au întors alți oameni decât cei care au plecat").
CONCLUZII: Cercetările indică faptul că TPST reprezintă o afecțiune psihiatrică importantă ce produce o suferință emoțională şi o inadaptare socială considerabilă, prezentând adesea un tablou clinic complex ce constituie o semnificativă provocare în ceea ce priveşte conduita terapeutică.

tulburare de stres posttraumatic **centru de recuperare** **militari şi angajați civili participanți la misiuni**

ABSTRACT
Purpose: The importance of study of Post-traumatic stress disorder (PTSD) in Romanian society, as a consequence of participation of Romanians troops in confliction areas.
Material and method: 3,2% of combatants were diagnosed with PTSD and were treated for this; 7% of combatants were diagnosed in time with PTSD, during another investigation; they justify "shame" and "fear" to admit disorder. Them family ask for support as well, as long as they can't communicate with them.
Conclusion: PTSD is an important psychiatric disease which can lead to endure and social inadaptability; it is a challenge in therapeutically assignment.
Key words: PTSD, recovery center, combatants

INTRODUCERE

„Şocul de bombardament" sau „sindromul de oboseală din timpul războaielor" cum a mai fost denumită tulburarea de stres posttraumatic (TSPT), se manifestă ca reacție la un eveniment catastrofal sever care se situează în afara limitelor experienței umane şi ar provoca oricui suferință. Tabloul clinic al TSPT este complex şi include simptome din sfera cognitivă, afectivă, fiziologică, comportamentală şi relațională. Terapia cognitiv-comportamentală, care pune un accent deosebit pe metode variate de expunere, s-a dovedit a fi cea mai eficace metodă de intervenție psihoterapeutică.

---

[*] Clinica de Psihiatrie, Spitalul Militar Clinic de Urgență „Dr. Iacob Czihac" Iaşi

Importanța cercetării în acest domeniu a devenit evidentă numai spre mijlocul anilor '70, când societatea americană s-a confruntat pentru prima dată cu problemele provocate de formele dezadaptative de comportament ale veteranilor războiului din Vietnam.

Datele obținute arătau că pentru aproximativ 25% din cei ce au luptat în Vietnam, experiența participării la acțiunile militare a fost cauza dezvoltării unor modificări negative de personalitate sub influența traumelor psihice.

Se estimează că peste 20% din totalul persoanelor care se întorc din taberele de război vor dezvolta TSPT şi că mult mai mulți vor dezvolta pe parcursul vieții tulburări psihice variate, de la depresie până la anxietate, vor trăi experiența divorțului, a consumului de droguri şi alcool, vor manifesta acte antisociale (Frank Ochberg, „Your Military Family Network”, 2007).

În 2005 cei aproape 216.000 de veterani ai SUA diagnosticați cu TSPT au beneficiat de 4,3 miliarde USD. Studiul din 2006 efectuat de revista Journal of the American Medical Association arată că 9,8% din combatanții din Irak s-au întors cu TSPT, iar 11,9% au dezvoltat TSPT în primul an de la întoarcerea acasă. În plus, peste 50.000 din veteranii din Irak şi Afganistan suferă de probleme mentale şi de sănătate, aproape jumătate dintre ei fiind diagnosticați cu TSPT; 22 dintre aceştia s-au sinucis, ridicând statistica la 1 din 5 necombatanți morți în 2005. În acest context Congresul SUA a cerut Departamentului Apărării să identifice şi să trateze membrii Serviciilor Armate suferinzi de TSPT.

În literatura de specialitate "stresul posttraumatic" sau "sindromul tulburărilor de stres posttraumatic" (TSPT) este descris ca fiind un stres întârziat şi care poate fi declanşat prin dezastre naturale, accidente grave, agresiuni, violuri şi alte evenimente critice cu impact traumatizant, atât fizic dar mai ales psihic.

Viața şi activitatea militară, în condiții de pace şi de criză şi cu atât mai mult în timp de război, constituie o sursă de trăiri emoționale pozitive şi negative complexe, niciodată univoce, uneori contradictorii sau ambivalente, dar întotdeauna aflate în situația de a genera şi de a menține stresul psihic.

Cercetările asupra stresului posttraumatic au debutat cu mai mult de jumătate de veac în urmă, încă în cel de-al doilea război mondial. Toate descrierile acestui fenomen includeau întotdeauna un şir de elemente comune: tulburări de somn, vise cu coşmaruri, depresii, excitabilitate crescută. Kardiner dă pentru prima dată o descriere complexă a simptomaticii acestui fenomen: 1) excitabilitate şi iritabilitate; 2) reacție nestăpânită la excitanți bruşti; 3) fixarea pe circumstanțele evenimentului traumatic; 4) fuga de realitate; 5) predispoziția pentru reacții agresive necontrolate.

În rezultatul cercetărilor a devenit clar că starea care se dezvoltă la cei ce au trecut prin situații critice generatoare de stres psihic (participarea la acțiuni militare, accidente, calamități naturale, diverse forme de violență) manifesta tendința nu numai să nu dispară cu timpul dar şi să devină tot mai pronunțată, debutând brusc pe fondul unei aparente bunăstări generale a persoanei.

Complexul de simptome ale tulburărilor cauzate de influența traumatizantă a diverşi factori stresanți asupra psihicului, de regulă ieşiți din comun în comparație cu experiența obişnuită a unui om, a fost descris în 1980 şi în DSM-III, ediția a 3-a, primind denumirea de sindromul tulburărilor de stres posttraumatic - TSPT. Caracteristic pentru sindromul descris este manifestarea sa tardivă, după o prelungită latență, putându-se vorbi de un stres psihic întârziat, şi faptul că sindromul poate fi intensificat prin alți factori stresanți adesea greu identificabili.

MATERIAL ŞI METODĂ

În DSM-IV[1] tulburarea posttraumatică de stres este definită prin şase criterii de bază:

(1) existența în antecedente a unui eveniment traumatic care implică atât iminența sau amenințarea cu moartea sau cu vătămarea importantă, cât şi un răspuns intens de frică, neajutorare sau groază;

(2) retrăirea persistentă a evenimentului traumatic prin intermediul amintirilor intruzive, a flashback-urilor disociative, a viselor chinuitoare recurente şi/sau a reactivității psihologice sau fiziologice la expunerea la unele activități sau situații care amintesc trauma;

(3) evitarea stimulilor asociați evenimentului sau o paralizare a responsivității generale, incluzând eforturile făcute de a evita gânduri sau sentimente legate de traumă, eforturi de a evita activități sau situații care trezesc amintiri ale traumei, pierderea interesului pentru activitățile importante, detaşare de alți oameni şi/sau tocire emoțională;

(4) existența unor simptome persistente ale unei stări de „hiperactivare" vegetativă ca, de exemplu, hipervigilență, tulburări de somn, iritabilitate sau izbucniri de furie, tulburări de concentrare şi/sau o reacție de surpriză exagerată;

(5) tulburarea are o durată de cel puțin o lună;

(6) efectele tulburării produc o suferință clinică semnificativă sau o afectare în funcționarea socială, ocupațională sau în alte domenii importante. Deşi simptomele TSPT sunt în mod obişnuit grupate în trei categorii primare (retrăire, evitare/paralizie, hiperactivare), simptomele tipice ce includ repetate retrăiri ale traumei împreună cu reactivitatea fiziologică asociată sunt cele care deosebesc cel mai bine TSPT de alte tulburări afective sau anxioase[2].

Haber şi colaboratorii[3] au constatat că tabloul clinic al TSPT include simptome din sfera cognitivă, afectivă, fiziologică, comportamentală şi relațională.

Dintre simptomele cognitive evidențiem următoarele: dificultăți de concentrare a atenției voluntare şi fixare a memoriei; retrăiri intense şi repetate ale experienței traumatice; prezența tulburărilor de senzorialitate (iluzii, halucinații); simptome disociative; amnezia psihogenă, incapacitatea de a-şi aminti aspecte importante ale traumei; evitarea gândurilor asociate cu evenimentul traumatic; vise cu coşmaruri repetate; percepție neobişnuită, adesea distorsionată a realității; afectarea viitorului în ceea ce priveşte profesia, orientarea profesională sau căsătoria; sentimente de autovinovăție; lipsa integrării cognitive a evenimentului traumatic perceput ca un factor de vulnerabilitate şi interpretare a unor situații neutre sau inofensive ca un pericol şi o amenințare; rezolvarea unor probleme se asociază cu crize de anxietate sau mânie.

În sfera afectivă putem regăsi următoarele simptome: stări de iritabilitate, explozii de mânie; disconfort intens apărut la confruntarea cu evenimente care simbolizează sau se aseamănă prin unele aspecte cu experiența traumatică; reducerea gamei reacțiilor emoționale; incapacitatea de a trăi sentimente de dragoste; anestezie emoțională sau tocire afectivă manifestată prin diminuarea capacității de răspuns afectiv; labilitate emoțională; sentimente de culpabilitate şi vinovăție; dispoziție depresivă, tristețe; stări de anxietate; incapacitatea de a trăi bucuria şi plăcerea unor activități relaxante.

Reacţiile fiziologice se pot manifesta astfel: dificultăţi la instalarea sau menţinerea somnului; răspuns exagerat în situaţii în care persoana este surprinsă sau speriată; reactivitate fiziolgică crescută în prezenţa unui stimul care reactivează amintirile, sentimentele sau senzaţiile asociate cu trauma; hipervigilenţă; modificarea parametrilor vitali prin creşterea frecvenţei cardiace şi a tensiunii arteriale.

În sfera comportamentală întâlnim o gamă de simptome variate, cum ar fi: evitarea fobică a situaţiilor care determină rememorarea evenimentului stresant; scăderea interesului şi reducerea participării în cadrul unor activităţi importante; fuga psihogenă manifestată prin calătorii neaşteptate departe de casă sau asumarea unor identităţi noi; nelinişte psihomotorie; dificultăţi în îndeplinirea sarcinilor cotidiene; schimbări ale stilului de viaţă sau a locuinţei; impulsivitate, episoade de agresivitate imprevizibilă; dependenţă medicamentoasă faţă de antialgice sau anxiolitice, utilizate pentru terapia disconfortului emoţional şi/sau a durerii fizice produse de evenimentele traumatice; abuz de substanţe psihoactive; tentative de autovătămare corporală.

În sfera relaţională se înregistrează o serie de simptome, de tipul: detaşare, înstrăinare şi izolare faţă de anturaj; afectarea capacităţii de trăire a sentimentelor de tandreţe şi intimitate; deteriorarea relaţiilor maritale şi parentale; distanţare excesivă exprimată în relaţionarea interpersonală cauzată de teama unei experienţe anterioare de trădare; evitarea unor dezvăluiri personale determinate de lipsa de încredere în alte persoane şi de teama de a fi respins.

Simptomele întâlnite în TSPT pot fi considerate, iniţial, o componentă a răspunsului normal al unei persoane la o experienţă copleşitoare. Dacă durata existenţei lor depăşeşte trei luni şi se prelungeşte o perioadă de luni sau ani de zile înseamnă că este vorba de o tulburare posttraumatică de stres. Indivizii care suferă de TSPT prezintă cel puţin un episod în care evenimentul traumatic revine în viaţa cotidiană. Uneori, acest fenomen se petrece brusc, evocarea revine clar în memorie şi se acompaniază de emoţii intense, dureroase. Alteori, se produce o retrăire a traumei în care amintirile sunt atât de puternice încât persoana revede scenariul traumei în faţa ochilor sau consideră că este vorba de o trăire autentică a traumei. Manifestările clinice descrise pot surveni în mod brusc, sub forma unui atac emoţional dureros, fără vreo cauză aparentă. Emoţiile pot exprima o stare de supărare care se însoţeşte de frică, mânie, crize de plâns. Experienţele emoţionale se produc în mod repetat sub forma reevocărilor evenimentelor traumatice sau a viselor cu coşmar.

În TSPT se manifestă pregnant fenomenul de evitare. Persoanele care au suferit traume se simt amortiţe, împietrite, evită relaţiile emoţionale cu familia, colegii de serviciu, prietenii şi îndeplinesc numai activităţile mecanice, de rutină, având o aparenţă rece, distantă, plictisită. Blake, Cook[4] descriu lipsa de afecţiune a acestor persoane faţă de propria familie, care se reflectă în conduita lor mecanică, inadaptată ambianţei. În acest context relatările membrilor familiei, ale prietenilor, ale colegilor de serviciu ajută la stabilirea diagnosticului şi a conduitei terapeutice.

Persoanele care prezintă TSPT evită situaţiile care le reamintesc de evenimentul traumatic, dezvoltând chiar o stare de teamă accentuată faţă de astfel de situaţii deoarece acestea pot agrava tabloul simptomatologic. Mulţi veterani de război refuză să accepte anumite responsabilităţi faţă de alte persoane, deoarece nu se consideră în stare să le asigure siguranţa şi protecţia lor. Alţii se simt vinovaţi pentru faptul că au supravieţuit dezastrului, în timp ce familiile lor sau prietenii au murit.

În studiile sale Symes[5] arată că depresia constituie o trăsătură comună a TSPT, ca o consecință a inabilității de rezolvare a emoțiilor dureroase, a stării de mânie şi supărare determinate de pierderile şi suferințele cauzate de evenimentul traumatic.

După încetarea acțiunii traumelor, comportamentul persoanelor cu TSPT este influențat în continuare de reacții emoționale dureroase, fără ca ele să conştientizeze acest lucru.

Starea de hiperexcitație cronică şi hipervigilență produce o modificare a comportamentului pacienților care suferă de TSPT, o scădere a capacității de concentrare a atenției voluntare şi de fixare a memoriei şi induce insomnii. Adesea, veteranii de război acționează într-un mod asemănător cu cel prezentat în perioada în care erau amenințați de traumă. Henry[6] arată că starea de hipervigilență întâlnită în TSPT determină o scădere a perfomanțelor profesionale şi o interrelaționare mai redusă cu familia şi prietenii.

Apariția unei reacții de alarmă biologică se exprimă prin declanşarea unor atacuri de panică, caracterizate printr-o teamă severă asemănătoare celei din timpul războaielor sau catastrofelor naturale, prin manifestări neurovegetative de tipul: epigastralgiilor, senzației de sufocare şi algiilor cefalice în cască[7].

Repartizarea celor mai semnificative simptome utilizate în evaluarea TSPT arată astfel:
1) prezența în anamneză a unei situații traumatizante (93% din experți i-au acordat nota cea mai mare);
2) întoarcerea permanentă la trăirile legate de circumstanțele traumei (78%);
3) visele şi coşmarurile pe tema traumei (77%);
4) amintirile obsesive (75%);
5) întoarcerile la situația traumatizantă prin asociații sau asemănarea circumstanțelor (73%);
6) "reactivitatea fiziologică" (mai mult de 66%).

METODĂ

Un model de tratament cognitiv-comportamental cu multiple componente este adecvat pentru majoritatea persoanelor cu TSPT. Acest model include un tratament multilateral destinat diverselor aspecte ale sindromului clinic asociat cu TSPT, cum ar fi reactivitatea emoțională şi fiziologică la anumite situații sau acțiuni care reamintesc trauma, simptomele intruzive şi comportamentul evitant, aptitudinile sociale deteriorate şi modularea emoțiilor (controlul furiei). Programul unifică abordarea terapeutică psihosocială a TSPT cu cea mai empirică susținere (terapia prin expunere) cu o componentă de exersare a aptitudinilor sociale şi a managementului anxietății[8].

Componentele principale ale acestui model sunt:

(1) Educația. Tuturor pacienților li se furnizează date generale despre TSPT cronică incluzând modalitățile frecvente de manifestare, problemele de diagnostic, comorbiditatea cu alte tulburări anxioase sau ale Axei I, etiologia şi o recapitulare a strategiilor actuale de tratament. Această componentă poate fi eficient realizată în 1-8 şedințe.

(2) Antrenamentul abilităților pentru managementul anxietății. Scopul acesteia este de a învață pacienții să-şi controleze anxietatea şi nivelurile stresului, inclusiv atacurile de panică. Exersarea aptitudinilor de management al anxietății poate servi unor funcții multiple şi probabil poate fi eficient realizată în 3-10 şedințe. Programele pentru suplimentarea terapiei prin expunere cu exersarea aptitudinilor de management al anxietății au fost cu succes realizate cu alte populații de victime ale traumelor[9] şi pot să includă elemente de exersare a relaxării, a respirației şi de control al panicii.

(3) Expunerea. Pacienţii trebuie expuşi la stimulii ce produc anxietate sau frică (legaţi de traumă) într-o maniera prelungită până există o reducere a fricii sau anxietăţii (până se obţine obişnuinţa sau stingerea) în cursul sedinţelor. Majoritatea persoanelor cu TSPT evită stimulii ce declanşează teama şi acest lucru ajută la creşterea intensităţii răspunsului de frică. Aşadar scopul expunerii este de a furniza un contact prelungit cu stimulii ce declanşează teama cu o durată suficientă ca obişnuinţa să se producă în cursul şedinţelor (o reducere cu 50% în reactivitatea din cursul şedinţei). Datele sugerează că această componentă poate fi eficient realizată în 4-15 şedinţe.

(4) „Temele pentru acasă". Componenta „temelor pentru acasă" (sau „practica programată") se poate aplica odată ce mai multe şedinţe de expunere au fost realizate cu succes şi reprezintă o formă de expunere care nu necesită prezenţa terapeutului. Trebuie imaginate experienţe care cer pacientului să se angajeze de la şedinţe de auto-expunere în imaginaţie realizate acasă care pot să servească drept pas iniţial către activităţile în vivo, ca de exemplu, vizionarea unor filme, discutarea cu alte victime ale traumelor sau cu persoanele dragi despre experienţele traumatice, etc. până la activităţi de care se teme şi care pot interfera cu calitatea vieţii: evenimente sociale (petrecerile, mesele împreună cu prietenii), cumpărături, mersul la filme, mese la restaurant, etc.

(5) Antrenamentul abilităţilor sociale. Scopul acestuia este de a forma abilităţi absolut necesare unor interacţiuni sociale eficace şi care pot antrena sentimentul de satisfacţie. Antrenamentul abilităţilor sociale poate fi deprins eficient în 6-15 şedinţe. Antrenamentul abilităţilor sociale vizează instruirea, modelarea, repetiţia comportamentală sau „jocurile de rol", feedback-ul şi întărirea. După fiecare şedinţă pacienţilor li se dau teme pentru acasă pentru a permite exersarea ulterioară şi consolidarea abilităţilor nou dobândite. Antrenarea abilităţilor sociale include următoarele elemente[10,11]:

Conştiinţa mediului social stabileşte nuanţele legate de când, cum şi de ce să iniţieze sau să întrerupă interacţiunile sociale. Aceasta include mecanismele verbale şi non-verbale ale întâlnirilor sociale de succes, incluzând identificarea unor subiecte de conversaţie adecvate, exerciţii specifice destinate să crească aptitudinile de atenţie şi ascultare, precum şi schimbările de subiect eficace[12].

Stimularea abilităţilor sociale urmăreşte formarea unor deprinderi de a iniţia şi de a menţine prieteniile, aptitudini adecvate pentru conversaţiile telefonice şi comunicarea asertivă. Această componentă este destinată să-i ajute pe pacienţi să înveţe acele abilităţi care le sunt necesare implicării în activităţi sociale diverse şi noi cu scopul de a-şi creşte repertoriul social şi posibilitatea ca interacţiunile sociale să devină intrinsec mai mulţumitoare[12].

Managementul furiei vizează controlul furiei şi al emoţiilor intense. Ar trebui să fie destinat reducerii izbucnirilor temperamentale şi manifestării problematice a furiei. În mod specific, această componentă trebuie să ajute prin a oferi pacienţilor o gamă de strategii pentru a-şi exprima furia, a-şi rezolva problemele, a-şi îmbunătăţi modularea emoţională şi a comunică asertiv cu ceilalţi, astfel încât violenţa fizică şi verbală să nu continue să le perturbe relaţiile sociale.

Managementul consecinţelor traumei îi învaţă cum să-şi îmbunătăţească comunicarea cu ceilalţi privind trauma, astfel încât să sporească înţelegerea acestora. Pacienţii trebuie învăţaţi cum să comunice asertiv când nu vor sau nu pot să discute cu alţii despre anumite subiecte sau evenimente. În plus, ei trebuie, de asemenea, învăţaţi să identifice şi să se opună modelelor de gândire negativă sau dihotomică (credinţa de a nu se încrede în toţi ceilalţi), ceea ce le limitează calitatea vieţii prin reducerea implicării în relaţii cu ceilalţi. În ultima instanţă, acest element trebuie să includă informaţii despre cum să evite să mai fie victime ale traumelor în viitor (sfaturi privind siguranţa personală).

Persoanele care dezvoltă simptomele TSPT nu trebuie să se aştepte ca 1-4 luni de terapie cognitiv-comportamentală intensă să „vindece" toate problemele. Mai curând tratamentul trebuie privit ca un mijloc de a ajuta pacienţii să-şi stăpânească şi să-şi controleze simptomele. Ţinând cont de acestea, este de aşteptat ca urmărirea continuă pe termen lung să fie necesară la majoritatea persoanelor cu TSPT.

CONCLUZII

Acest demers demonstrează că tulburarea de stres posttraumatic este o problemă a societăţii româneşti care, neglijată, poate avea consecinţe negative pe termen mediu şi lung asupra calităţii vieţii militarilor şi personalului civil angajat participant la misiunile din teatrele de război şi a familiilor acestora.

În acest scop propunem înfiinţarea unor centre pentru TSPT care să se adreseze acestei categorii sociale şi care să aibă drept scop:

- consilierea şi pregătirea psihologică a participanţilor în misiune, 3-4 zile;
- asigurarea îngrijirii medicale şi a reinserţiei sociale a participanţilor la misiuni;
- oferă educaţie şi pregătire în gestionarea stresului posttraumatic şi a altor tulburări legate de stres, stimularea resurselor şi a readaptării la mediul socio-profesional;
- informarea, educarea şi consilierea psihologică a familiilor;
- monitorizare pe o perioadă de 1 an de zile prin prezentări periodice (o dată la 3 luni sau la solicitare).

Considerăm că tratamentul şi recuperarea în TSPT poate fi realizată mult mai eficient imediat după revenirea din misiunile speciale, împreună cu familia, aproximativ o lună de zile într-o zonă cu caracteristici balneo-climaterice sedative, favorabil persoanelor sănătoase sau cu stări de surmenaj.

Aceste caracteristici bioclimatice, precum şi dotările moderne pentru recuperarea medicală (instalaţii pentru electroterapie, afuziuni, duşuri scoţiene, duş-masaj, duş subaqual, saună, aerosoli, sală de cultură fizică medicală şi recuperatorie, bazin de hidrokinetoterapie, băi cu apă clorosodică caldă, băi galvanice şi împachetări cu nămol de sendiment) sunt argumente care susţin înfiinţarea unui asemenea centru în staţiunea Bălţăteşti.

Complianța la tratament a bolnavilor TB, cheia succesului terapeutic

Drd. dr. Manuela GHEORGHIU-BRANARU[*]
Prof. asoc. Cristian DIDILESCU*

OBIECTIV: Tuberculoza reprezintă o problemă prioritară a sănătății publice în România. Controlul tuberculozei trebuie să devină astfel o prioritate a politicii de sănătate a Guvernului şi a programului de dezvoltare socio-economică pe termen mediu şi lung.
Creşterea complianței pacienților la tratamentul antituberculos în condiții de ambulator de specialitate a devenit o problemă în lumea medicală de specialitate, datorită importanței fenomenului „tuberculoză", în țară şi în lume. Dezideratul se poate materializa prin eforturi conjugate, strict medicale, coroborate cu acțiuni socio–economice, prin acordarea de stimulente sau facilități, în scopul creşterii gradului de aderență la tratament, ca urmare a eforturilor sporite de ridicare a nivelului de educație de sănătate şi a comunicării între pacient şi cadrele medicale.

tratament sub directa observare Strategie Națională de Control a tubercuzei complianță

ABSTRACT: Tuberculosis is a priority Public Health problem in Romania. Therefore, the control of tuberculosis must be a priority of the Government health policy and of the social and economical development programme on long-intermediate term.
The compliance development of the patients at the anti-phthisical treatment, in conditions of the out-patients department has been a problem in the medical specialty world because of the importance of „tuberculosis" phenomenum in the country and in the world. This wish can be achieved by uniting strictly medical efforts, corroborated with socio-economical activities, by according some stimuli or facilities, with the purpose of developing the adherence to the treatment, as a result of the increased efforts to increase the level of health education and communication among the patient and the medical staff.
Key words: tuberculosis, treatment under direct observation, National Strategy of Tuberculosis Control, compliance.

Strategia Națională de Control al Tuberculozei se încadrează în Strategia de țară a României privind atingerea până în 2015 a obiectivelor de dezvoltare ale mileniului (2015 MDGs) şi oferă cadrul necesar dezvoltării şi armonizării legislației şi reglementărilor naționale cu cele europene.

După adoptarea, începând cu anul 1998, a strategiei internaționale de tratament sub directă observație (DOTS) şi implementarea Programului Național de Control a Tuberculozei 2001-2005 (PNCT), România înregistrează in 2003, pentru prima dată în ultimii 20 de ani, o tendință de scădere a cazurilor noi de tuberculoză.

Scopul Strategiei Naționale de Control a Tubercuzei 2006-2010 este de a contribui la îmbunătățirea stării de sănătate a populației României, prin reducerea morbidității şi mortalității prin tuberculoză şi limitarea cât mai rapidă a răspândirii infecției şi bolii în populație, având la bază recomandările experților OMS, precum şi direcțiile strategice din Planul Global de Stopare a Tuberculozei 2006-2015.

Tuberculoza continuă să îsi etaleze istoria de peste 3000 de ani, infectând în momentul prezent o treime din populația globului şi ucigând aproximativ 2 milioane de oameni anual.

---

[*] Ambulatoriul de specialitate - Institutul de Pneumoftiziologie „Marius Nasta", Bucureşti

Această boală rămâne în continuare să țină prima pagină a patologiei infecțioase de pe întreg mapamondul.

Se estimează că în ultimul deceniu al secolului trecut s-au înregistrat în lume peste 32 milioane de noi îmbolnăviri TB şi peste 10 milioane decese datorate TB; mai mult de 8 milioane de oameni fac TB/an şi aproximativ 2 milioane mor. Se apreciază că numărul cazurilor TB va crețte în ciuda eforturilor care se fac pentru controlul acestei boli şi va ajunge în 2020 la circa 10 milioane cazuri noi/an.

Dacă această boală nu va fi controlată în viitor, se estimează ca în perioada până în 2020, aproximativ 1000 milioane de oameni se vor infecta cu BK, peste 150 milioane vor face boala, iar 36 milioane vor deceda.

Distribuția geografică a tuberculozei este diferită de la un continent la altul şi chiar de la o țară la alta, incidența cea mai ridicată înregistrandu-se în Africa şi Asia.

În regiunea Europa, 16 din 51 țări se confruntă cu creşteri dinamice ale incidenței în ultimii 10 ani. În aceste țări se concentrează 77% din întreaga endemie europeană. România este pe locul 3 ca gravitate a endemiei. Cu toate că există o strategie numită DOTS, tuberculoza continuă să facă victime.

Tuberculoza reprezintă o importantă problemă de sănătate publică în România. Conform statisticilor WHO, în România sunt raportate zilnic 82 cazuri noi la adulți, 5 la copii şi 5 decese.

Tuberculoza afectează în principal populația activă a țării, înregistrându-se aproximativ 400 pacienți TB %oo, cu vârste între 45 - 49 ani.

Bolile contagioase care au fost controlate eficient în România, au reaparut în ultimii 10 ani, incluzând creşterea abruptă a frecvenței TB, ajungând de la 70%oo în 1990, la 138,7%oo în 2002, urmată de o scădere uşoară până în prezent.

Una din cauzele majore ale creşterii incidenței este complianța scăzută la tratamentul greoi şi de lungă durată. Deşi nimeni nu poate fi declarat vinovat că s-a îmbolnăvit de tuberculoză, de regulă, aceşti bolnavi nu sunt bine priviți în societate. Omul sănătos se teme să nu se îmbolnăvească şi, de aceea, când află de o rudă, coleg ori prieten că are tuberculoză, neştiind cum să se protejeze, se arată ostil față de pacient.

Există mentalitatea că TB e o boală ruşinoasă, încât pacientul sau familia se feresc să popularizeze situația. Sunt oameni cărora le vine greu să conceapă faptul că suferă de TB. Asta nu face decât să întârzie prezentarea la medic şi începerea tratamentului, timp în care pot infecta alte persoane.

Probleme apar şi la reintegrarea în muncă – este primit cu rezervă de colegi şi anturaj. Realitatea însă este alta: un pacient tratat corect se vindecă şi poate avea o viață absolut normală.ținând cont de plurifactorialitatea transmiterii acestei boli.

Este necesar să identificăm resursele necesare în vederea utilizării lor cu un raport cost-eficiență optim.

Tuberculoza este o boală care se poate preveni şi trata prin intervenții coordonate la nivel național şi local.

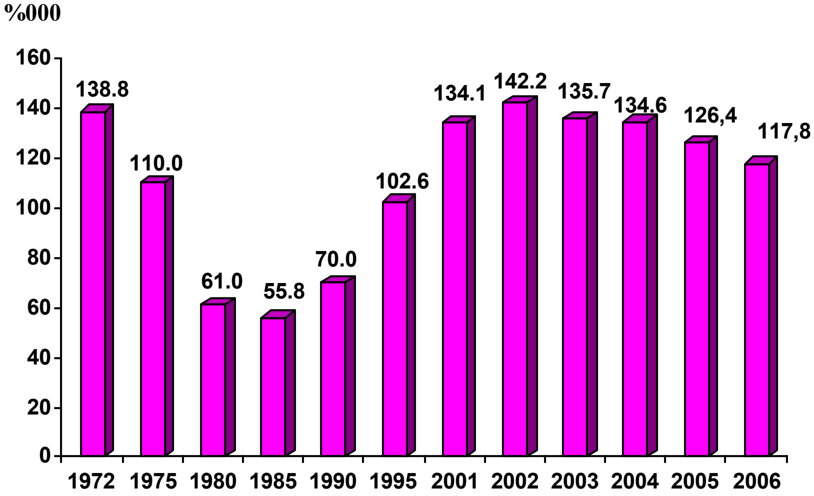
Lupta împotriva tuberculozei se abordează multidisciplinar şi intersectorial.

DATE EPIDEMIOLOGICE

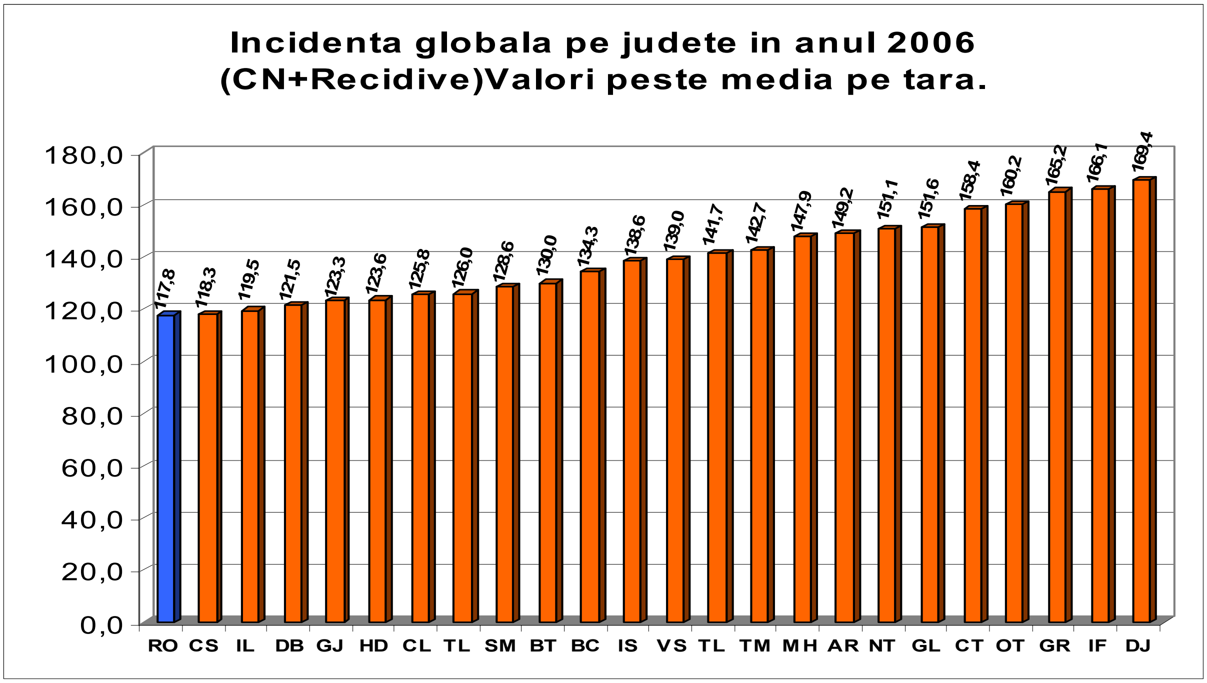
Analiza datelor statistice arată, conform previziunilor, o scădere a incidenței tuberculozei în țara noastră, în ultimii ani.

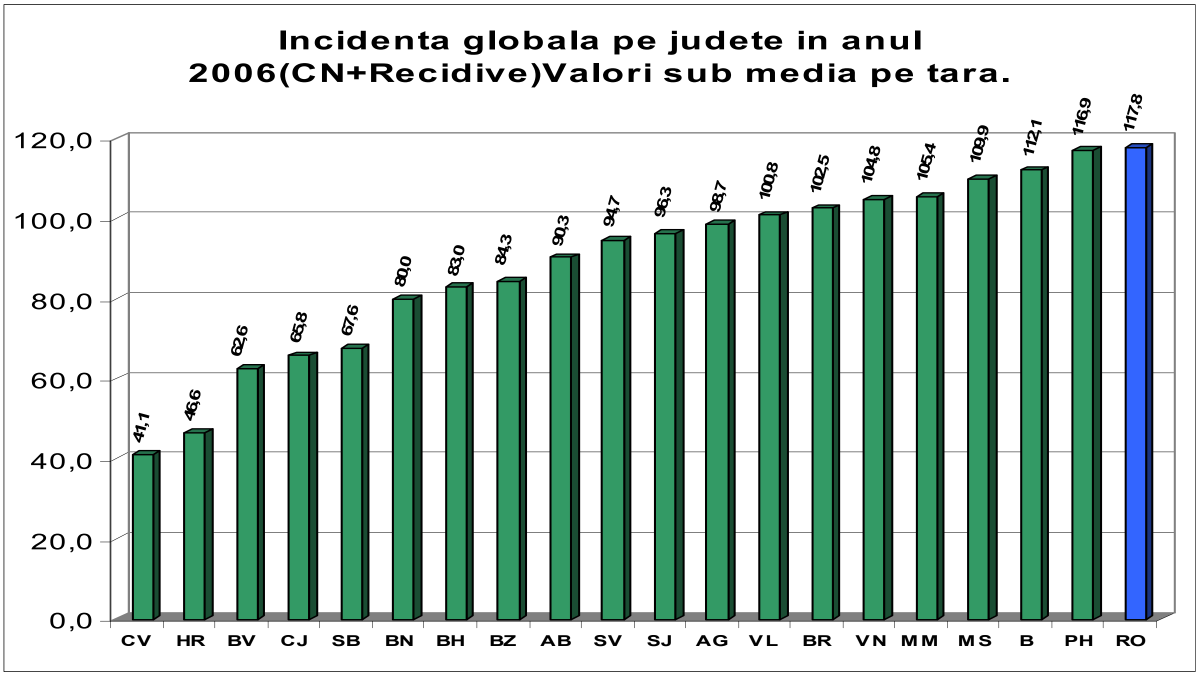
Incidența în rândul populației generale a scăzut de la 138,8%00 în 1972 la 117,8 %000 locuitori în 2006, în timp ce media europeana este de 50 la 100.000.

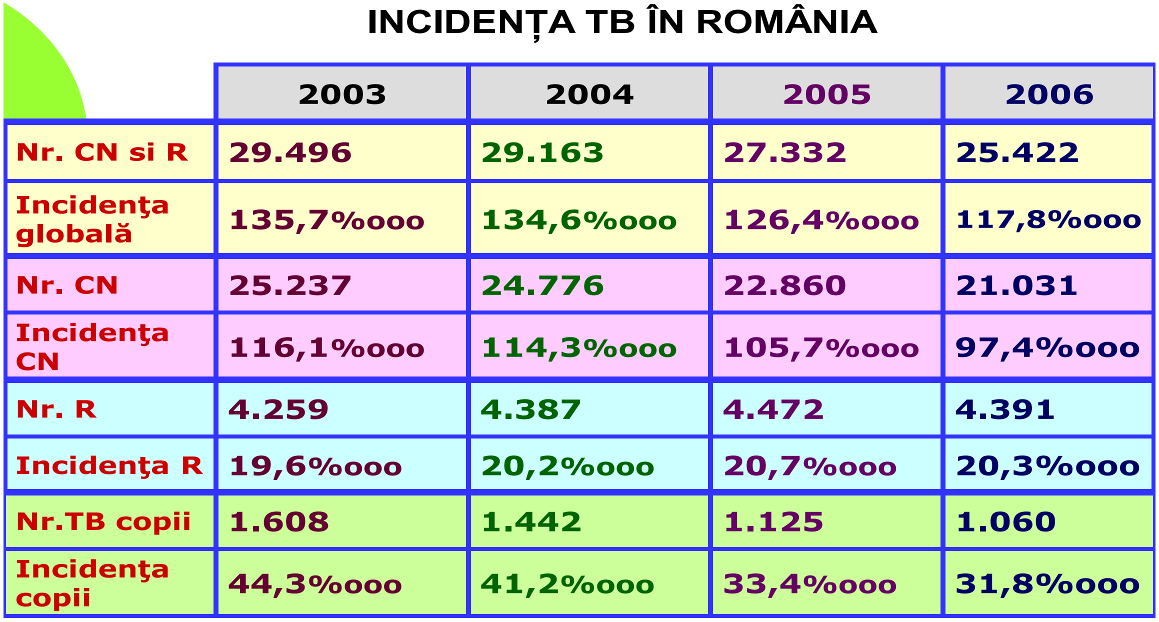
Evolutia incidenţei TB 1972 – 2006



Iată în continuare situaţia incidenţei globale, pe judeţe, în anul 2006, Bucuresti-ul aflându-se uşor sub medie, pe primele locuri fiind judeţele Dolj, Ilfov şi Giurgiu.







INCIDENȚA TB ÎN ROMÂNIA

	2003	2004	2005	2006
Nr. CN si R	29.496	29.163	27.332	25.422
Incidenţa globală	135,7%ooo	134,6%ooo	126,4%ooo	117,8%ooo

Nr.TB copii	1.608	1.442	1.125	1.060
Incidenţa copii	44,3%ooo	41,2%ooo	33,4%ooo	31,8%ooo

Această situație încurajatoare se datorează unui tratament eficace şi eficient, aplicat în condițiile sistemului DOT.

Caracteristicile acestui sistem, care îi conferă greutate şi credibilitate, sunt următoarele:

- Are tradiție încă din anii ’50 (sistem de înregistrare şi raportare a tuturor cazurilor de TB);
- Anii ’70: TSS (prefigurarea strategiei DOTS);
- 1998: instituirea strategiei DOTS în regim pilot;
- 2005: 100% acoperire cu DOTS;

- Urmăreşte recomandările OMS;
- Beneficiază de asistență tehnică din partea OMS;
- TB - prioritate de sănătate publică;
- Diagnosticul şi tratamentul TB sunt gratuite!
- Programul Național de Control al Tuberculozei este ordin al Ministrului Sănătății Publice.

Obiectivelele generale ale Strategiei Naționale a României de Control a Tubercuzei 2006-2010 sunt definite pentru atingerea Țintelor Globale propuse de către Planul Global de Stopare a Tuberculozei 2006-2015 (Obiectivele de Dezvoltare ale Mileniului):

1. Menținerea acoperirii 100% cu DOTS a populației afectate de tuberculoză;
2. Menținerea detectării a cel putin 70 % din totalul cazurilor de tuberculoză, până în 2010;
3. Extinderea şi menținerea ratei de succes terapeutic a cel putin 85% din totalul cazurilor noi de tuberculoză pulmonară, până în 2010.

Serviciile de sănătate de prevenire, diagnostic, tratament şi suport psiho-social în domeniul tuberculozei trebuie sa conlucreze si să fie accesibile, acceptabile şi eficace.

Strategia administrării tratamentului sub directă observare (DOT) este parte componentă a strategiei globale de control a tuberculozei (DOTS).

O atenție specială trebuie acordată grupurilor populaționale vulnerabile şi comunităților afectate (populația cu nivel socio-economic şi educațional scăzut, populația romă, deținuții, etc.), grupurile populaționale speciale, pentru intervenții specifice (persoanele infectate HIV care dezvoltă şi tuberculoză (HIV/TB), persoanele care efectuează tratamente imunosupresoare, pacienții cu tuberculoză rezistentă (MDR/TB).

Adminstrarea tratamentului poate fi plăcută atât pentru pacient cât şi pentru terapeut. Dacă pacientul simte că este tratat cu considerație, se poate dezvolta o relație ce va avea repercursiuni pozitive asupra comportamentului pacientului în administrarea DOT, dar şi pe termen lung, în viață.

Din păcate, non-complianța este un fapt dovedit cu care ne confruntăm. Un program coerent trebuie să se centreze pe pacient şi să țină cont de nevoile sale, diferențiat.

Asigurarea unui suport material al pacienților TB, în condițiile de afectare a unui individ prin această boală, determină îndepărtarea, sau marginalizarea din sfera preocuparilor de moment , cu dezinsertie sociala, profesionala şi familială, până la negativare şi reluarea activităților curente, poate creşte complianța la tratament.

Personalul care se ocupă de pacienții TB se confruntă cu probleme serioase pentru a obține complianța la tratament, cea mai gravă consecință fiind extinderea tuberculozei rezistente la tratament. Acest lucru reprezintă un argument major în sprijinirea ideeii ca pacienții TB, care nu-şi urmează corect şi complet tratamentul, trebuie să fie atent şi permenent monitorizați în privința complianței, iar măsurile trebuie rapid instituite.

ISTORIA NATURALA A FENOMENULUI

Dovezi istorice ale non-compliantei

Grupuri de risc la non-complianti

Personalul implicat în administrarea DOT apreciază non - complianța între 25-80%! Nu există un anumit grup sau categorie socială care să poată fi identificată ca având risc maxim de non-complianță. Chiar cei mai bine educați membrii ai societății pot deveni non-complianți, ținând cont de perioada lungă de tratament.

Nici sărăcia, nici locuința sub standard, nu înseamnă că aceşti pacienți sunt lipsiți de inițiativă şi nu vor copera. Nu există un element predictiv pozitiv al complianței.

În practica de zi cu zi rezultă că anumite modele comportametale sau informații anamnestice despre pacienți pot fi utile în prezicera complianței.

Din experiență ştim că urmatoarele grupuri de pacienți necesită o urmărire mai atentă, având un risc crescut de non-complianță:

- ✓ Eşecuri terapeutice anterioare. Persoanele care au eşuat anterior în completarea curelor terapeutice anti - TB sau a altor tratamente au risc înalt.
- ✓ Toxicomanii. Indivizii care abuzează de droguri de orice fel, suferă o alterare a stărilor cognitive şi prioritățile sunt inversate. Nu se renunță la starea de bine legată de drog în favoarea unui tratament coerent, care uneori provoacă chiar stare de rau! Mulți pacienți acuză greață şi vărsături cînd consumă alcool şi iau medicamente anti-TB.
- ✓ Afecțiuni mentale, emoționale, psihice, nedeclarate la persoane care nu înțeleg importanța tratamentului şi refuză medicamentele sau sunt susceptibile de a lua supradoze, ori au afecțiuni fizice care împiedică înghițirea medicamentelor (stricturi esofagiene).
- ✓ Persoanele care ar trebui să fie cele mai demne de încredere. Cel mai frustrant grup pentru personalul medical, deoarece riscul de non-complianță pare inițial mic, au intenții bune dar interesul scade o dată cu timpul. De regulă sunt oameni respectați în comunitate, instruiți, dornici de informații, politicoşi, punctuali, dar cu diferite slăbiciuni, cea mai neplăcută fiind faptul că nu îşi iau medicația conform prescripțiilor.
- ✓ Pacienții ostentativ cinstiti. Aceştia recunosc de la început dificultatea de a înghiți pastilele şi o mărturisesc. Deşi frustranți, atrag atenția personalului medical ceea ce, pe termen lung, economiseşte timp.
- ✓ Pacienți cu relații de slabă calitate cu personalul medical. Relația personal medical – pacient poate fi uneori stresantă. Studiile medicale nu dau şi certitudinea că se vor înțelege şi se vor agrea. Uneori pacientul preia „comanda” în detrimentul tratamentului.
- ✓ Alte situații sunt acelea în care pacienții ce primesc medicamentele dar trişează şi nu le înghit, dar vor să se asigure totuşi de eventualele beneficii obținute prin acordarea de stimulente.

MASURI IN ATITUDINEA FATA DE PACIENTII NON-COMPLIANTI

Există diferite căi prin care să poată fi realizată ameliorarea stării de complianță a pacientului la tratament, în scopul realizării DOT complet, cu consecințe favorabile pe termen lung asupra incidenței tuberculozei.

1.Educația pentru sănătate presupune:

- Educația individuală;
- Organizarea întrunirilor publice;
- Campanii media;
- Sprijinul autorităților publice locale şi poliție;
- Codul penal: Art. 383;
- Protocolul MSF - CNAS legat de tratamentul bolnavilor TB neasigurați/asistați social.

2.Ameliorarea relației pacient-terapeut

Tratamentul TB este lung şi plictisitor. Poate fi uneori agravant, prin reacțiile adverse la medicație. Pacientul trebuie să treaca peste aceste greutăți cu ajutorul cadrelor medicale, care trebuie să dezvolte şi să mențină o legătură solidă cu pacientul bazată pe comunicare clară şi eficientă, după un plan stabilit de terapeut de comun acord cu pacientul.

TB este o boală complexă. Personalul medical are nevoie de timp pentru a înțelege nevoile pacientului. Între pacient şi medic există o asimetrie informațională care pune pacientul în inferioritate: medicul trebuie să aibă capacitatea de a furniza pacientului informațiile de care are nevoie şi pe care le poate prelucra la nivelul său de cunostinte.

Din acest motiv, medicul trebuie să ştie şi să poată să se adapteze în permanență pentru ca, în cele din urmă, relația medic – pacient contează în completarea adecvată a terapiei.

Vor trebui făcute eforturi pentru a evita animozitățile între terapeut şi pacient; chiar dacă pacientul omite o doză, nu trebuie să se simtă pedepsit.

Atitudini de urmat:

- Îmbunătățirea canalelor de comunicare cu pacientul şi familia;
- Înțelegerea importanței tratamentului;
- TB se trateaza şi se vindecă;
- Folosirea unui vocabular tehnic adecvat;
- Eliminarea diferențelor culturale;
- La nevoie, constrângeri instituționale;
- Probleme de control.

3.DOT

Un pricipiu de bază este acela că dacă vrem să fim siguri că pacientul ia medicamentele, trebuie să privim la el când înghite. Deci strategia cea mai eficientă este DOT sau TSS. De aceea, pacienții trebuie convinşi să vină la cabinetul special destinat acestei activități. Un cadru medical face o evaluare profesională pacientului în vederea includerii în DOT. În funcție de complexitatea cazului şi de starea fizică a pacientului, asistenta medicală va administra DOT sau va delega altă persoană.

DOT-ul se administrează de 3 ori pe săptămână, la pacienții în faza de continuare a tratamentului standard sau zilnic, la pacienții cu TB-MDR, cu regimuri individualizate, de lungă durată.

Membrii personalului medical trebuie instruiți cu privire la asumarea responsabilității monitorizării tratamentului şi a complianței pacienților. Trebuie reținut că DOT-ul este o intervenție pozitivă şi nu punitivă, deci pacientului i se va explica necesitatea acestui tratament.

Este necesar crearea unui suport material pentru pacient, în condițiile în care afecarea unui individ prin TB determină îndepartarea din sfera preocupărilor obişnuite (sociale, profesioanele, familiale) urmat de dezinserție până la neglijare.

METODE DE REALIZARE ŞI IMPLEMENTARE A STRATEGIEI DOT

- **A crede în DOT**. Pentru a putea realiza DOT este nevoie în primul rând să credem în el şi în eficiența sa, deja dovedită. O atitudine pozitivă va da încredere pacientului că se află pe mâini bune.
- **Unde ?** Administrarea se face la cabinete special amenajate, cu personal special instruit în acest domeniu. Programul va fi flexibil pentru a putea asigura accesibilitate tuturor pacienților. Dacă pacientul nu poate veni la cabinet, trebuie să se găsească metode de a i se duce tratamentul la domiciliu. Consemnarea administrării prizelor de tratament se face pe foi speciale, unde sunt înscrise şi omisiunile, schimbările de tratament şi reacțiile adverse.
- **Confidentialitatea**. Se administrează tratamentul acolo unde se simte bine pacientul în condiții de confidențialitate absolută.

- **Delegarea**. În cazul în care pacientul nu poate ajunge la cabinet, se va găsi o persoană pentru a fi delegată să administreze tratamentul (asistent social, comunitar, rudă, vecin, etc.), după o prealabilă instruire şi transfer de responsabilitate.
- **Utilizarea de stimulente**. Unul din cele mai eficiente programe, utilizate astăzi în multe strategii de control al TBC este recurgerea la stimulente şi ajutoare pentru a încuraja completarea terapiei. Stimulentele sunt mici recompense date pacienţilor, pentru a-i stimula să-şi ia medicamentele sau să-şi respecte programările (la cabinetul medical sau acasă – pentru TSS). Ajutoarele sunt acele lucruri care "ajută" pacientul să-şi primească tratamentul (ca de ex.: bilete de autobuz, bani de taxi, baterii pentru maşină sau bani pentru babysitter astfel încât mama să se poată duce la cabimetul medical să-şi poata lua medicatia).

Stimulentele pot fi mici sau mari, pot fi alimente, bunuri sau servicii. Ceea ce reprezintă un stimulent pentru un pacient poate să nu reprezinte nimic pentru altul. De aceea, stimulentele trebuie adaptate fiecărui individ, altfel sunt ineficace. Un pacient căruia îi este foame va fi atras de unele alimente. Un pacient friguros va aprecia o pereche de ciorapi călduroşi sau un pulover. Unui copil i-ar plăcea o vizită la cofetărie cu sora sa sau sa-i fie citită o poveste. O mamă ar putea fi motivată de cadouri pentru copii ei, de exemplu caiete şi creioane pentru şcoală. Un buchet de flori este o pată de culoare în ziua unui pacient vârstnic.

Terapeutul, care este deosebit de sensibil la neovile fiecărui pacient, este cel care va avea cel mai mare succes în utilizarea stimulentelor şi ajutoarelor pentru completarea terapiei. După cum au constatat multe surori medicale, asistenţi sociali şi alţi terapeuti, că nu contează atât ce i se dă pacientului cât îi dai din tine insuti. Faptul că îti dai osteneala să alegi ceva semnificativ şi special pentru acea persoană este imediat înteles chiar de pacientul cel mai indiferent. Mulţi pacienţi, care luptă să-şi impună controlul asupra programului terapeutic şi care fac necazuri personalului, nu au avut niciodata o relaţie adevărată cu cineva. În consecinţă, utilizarea stimulentelor şi dăruirea de sine, devine o experienţă care schimbă viaţa, atât a pacientului cât şi a terapeutului.

Modalităţi de realizare practică:

- Educaţie de sănătate;
- Utilizarea aşa-ziselor carduri de memorie;
- Utilizarea stimulentelor constând în alimente, bonuri valorice, bani, îmbrăcăminte, articole de utilitate casnică, în scopul creşterii aderenţei la DOT;
- Administrarea medicamentelor la domiciliu, de către personalul medical, prin deplasare cu maşina din cadrul programului;
- Administrarea medicamentelor la domiciliu, de către o persoană din familie, instruită în acest sens;
- Administrarea medicamentelor la domiciliu prin intermediul unor asistenţi sociali sau comunitari, special instruiti;
- Acordarea de bilete de transport pentru facilitatea ajungerii la cabinetul medical;

Aplicarea unor metode de stimulare a complianţei la tratamentul antituberculos are ca rezultat negativarea pacientilor, vindecarea lor şi eliminarea surselor de îmbolnăvire. Consecinţa pe termen mediu şi lung este diminuarea focarelor epidemiologice TB şi scăderea endemiei tuberculoase.

Posibilatea generalizării la scară naţională ar putea deschide noi perspective asupra administrării strict supravegheate a tratamentului şi corectarea unor elemente ce se vor dovedi rentabile sub aspectul cost/beneficiu.

Studii făcute deja la noi în ţară, au fost derulate prin proiecte Global Fund, DOW si Crucea Rosie Romana (CRR). DOW şi CRR au colaborat cu succes la implementarea unui proiect în parteneriat, în anul 2005, intitulat *„Stabilirea unui sistem de distribuire de stimulente pentru îmbunătațirea tratamentului la pacienții TB în București, Ilfov şi Constanța”.* În cadrul proiectului au fost distribuite pacienților bonuri valorice pentru cumpărarea de alimente, în functie de consecvența prezentării la DOT. Acest proiect a fost reluat în august 2006 de CRR si extins în toată țara.

Un alt proiect realizat de organizația *Rromanicriss* a vizat formarea de mediatori comunitari care să activeze în raza sectoarelor 1 şi 6 din Bucureşti şi în județele Tulcea, Galați şi Giurgiu, demarat în 2005 şi derulat în continuare. Mediatorii sunt instruiți să poată furniza educație de sănătate precum şi informații pertinente despre tuberculoză în comunitățile de rromi şi nu numai, să administreze DOT la domiciliul pacienților nedeplasabili sau să recupereze pacienții TB.

Alt proiect în derulare aparține Samu-Social şi se referă la pacienții fara adăpost, suferinzi şi de tuberculoză.

Dezvoltarea unei strategii naționale pe termen mediu privind informarea- educarea-comunicarea în vederea schimbării comportamentelor, atragerea de resurse financiare şi colaborări cu instituții specializate în vederea implementarii IEC

Administrarea medicamentelor în tuberculoză, reprezintă cheia de boltă pentru succesul terapeutic. Tratamentul fiind de lungă sau foarte lungă durată, cu aasociere de mai multe medicamente, este greu de acceptat de catre pacient. De aceea s-au căutat mereu soluții pentru atragerea pacienților şi creşterea complianței la tratament.

În prezent se experimenteaz regimuri **noi** de tratament aflate încă în faza de studiu clinic, de scurtă durată (4 luni şi administrare zilnică) având o chinolonă administrată pe toata durata tratamentului.

Organizarea tratamentului trebuie să vizeze programarea administrării dozelor, convenabil pentru pacient, folosirea de stimulente, obținerea suportului familiei, îndrumarea pacienților către programe de asistenttă sau consiliere în caz de alcoolism, consum de droguri, probleme de sănătate mintală.

Principiile de tratament în tuberculoză au în vedere utilizarea combinațiilor de medicamente antituberculoase recomandate, administrarea lor sub directa observație, educarea pacientului şi familiei în sensul că numai un tratament CORECT şi COMPLET asigură vindecarea şi previne recidivele, atitudinea amabilă şi prietenoasă a personalului medical.

Posibilele cauze de întrerupere a tratamentului sunt: abuzul de alcool şi droguri, frica sau refuzul de a fi etichetat ca bolnav de tuberculoză, dispariția simptomelor bolii, neînțelegerea importanței tratamentului, motivele personale sau culturale (ex. tratamente alternative), efectele adverse, lipsa speranței de vindecare şi reintegrare, pacienți vârstnici sau cu boli mintale, probleme medicale asociate, teama de şomaj datorat bolii, relația defectuoasă cu personalul medical.

Atitudinea cadrelor medicale, în cazul întreruperii tratamentului, trebuie să cuprindă acțiuni care vizează convingerea pacientului să reia tratamentul.

Creşterea aderenței pacienților TB la trament implică, în primul rând, o foarte bună comunicare cu pacientul şi implicit o bună educație de sănătate a acestuia. Pacientul TB trebiue să înțeleagă boala pe care o are, să capete informații în acest sens, să cunoască tratamentul şi implicațiile acestuia, precum şi repercursiunule asupra semenilor săi, în cazul refuzului tratamentului. Pacientul poate renunța cu uşurință la tratament după 2-3 luni, mai ales în cazul în care începe să se simttă foarte bine, fapt ce ridică riscul recidivelor şi/sau al cronicizării bolii, până la transformarea în forme de tuberculoză MDR.sau chiar X-DR.

Implicațiile de ordin epidemiologic şi social sunt enorme, în cazul în care pacienților nu le sunt explicate aceste lucruri. Pe de altă parte, pentru ca pacienții ce au primit deja bagajul de informații de educație de sănătate, să accepte mai uşor tratamentul de lungă durată şi cu multe droguri, peste tot în lume se recurge la diferite modalități de stimulare a prezenței la tratamentul strict supravegheat.

În general se caută modalităţi şi metode în concordanţă cu nevoile pacienţilor sau se adaptează la specificul situaţiei din ţara respectivă.

Istorie, prezent şi perspective pentru sănătate

Lt. Col. Ec. Panaite GRECU *

Nemţenii, locuitori ai Moldovei din cele mai vechi timpuri, au fost şi sunt creatori şi păstrători de autentică istorie.

Uniţi prin tradiţiile şi obiceiurile bine cunoscute din evocările lăsate de Ion Creangă, în ale sale „Amintiri”, locuitorii Depresiunii Neamţului au fost favorizaţi de un relief deluros, cu mici platouri şi pante domoale, pretabil habitatului sedentar, agriculturii; clima blândă, pânza freatică bogată în apă potabilă şi apă de sărătură, prezenţa unor întinse păduri au contribuit la dezvoltarea, în general a vieţii şi comunităţilor locale şi în particular a meşteşugurilor şi altor îndeletniciri ce au la bază prelucrarea lemnului, pietrei, cerealelor, fructelor, cărnii, lânii şi nu numai.

În microregiunea Târgu Neamţ, descoperirile arheologice confirmă pe deplin existenţa umană, încă înainte de Hristos; şantierele arheologice de la Ghindăoani, Tărpeşti, Davideni, au scos la lumină numeroase vestigii: monede, arme, unelte, locuinţe şi lăcaşuri de cult, morminte, toate de mare însemnătate istorică şi care conduc cu certitudine la concluzia că aceste teritorii sunt locul unei culturi şi civilizaţii străvechi.

Localitatea Bălţăteşti a fost atestată documentar din vremea Domnitorului Constantin Movilă care printr-un act de donaţie datat 01 septembrie 1608 donează vornicului său Pătraşcu „Satul domnesc Bălţăteşti.

În anul 1716, satul apare pentru prima oară pe o hartă, aceasta aparţinând Domnitorului Dimitrie Cantemir fiind intitulată „PRINCIPATUS MOLDAVIAE NOVA & ACCURATA DESCRIPTIO”, hartă unicat aflată în prezent în patrimoniul Bibliotecii Naţionale din Paris.

În perioada 1715-1849 Bălţăteştiul constituie sursa neînţelegerii privind dreptul de proprietate între familia Cantacuzino şi Mănăstirea Hangu.

În anul 1864 Bălţăteştiul trece în proprietatea domnitorului Dimitrie Barbu Ştirbei care o atribuie ca zestre fiicei sale Contesa Martha de Blöme.

În anul 1839 doctorul I. Chihac şi profesorul E. Humpel efectuează pentru prima oară analiza apelor minerale de Bălţăteşti extrase din trei fântâni de saramură; ulterior în 1850 cunoscutul savant român Petre Poni analizează aceste ape şi le stabileşte compoziţia chimică; toate aceste analize scot în evidenţă existenţa în conţinutul apelor de Bălţăteşti a unor cantităţi însemnate de sodiu, clor, magneziu, calciu, fier, potasiu, iod, acid clorhidric, bromură de magneziu, sulfaţi. Având la bază aceste analize, Principele Ştirbei, proprietar al Băilor, face considerabile investiţii pentru punerea în valoare a calităţilor curative şi de balneaţie ale celor trei izvoare de apă sărată, botezate: Olga, Elena şi Gheorghe.

Pe data de 19 octombrie 1878 doctor Dimitrie Cantemir, descendent al domnitorului moldovean, cumpără de la Principele Dimitrie Ştirbei băile , „Stabilimentul de slatină” compus dintr-o clădire principală în formă de potcoavă, şase bucătării şi şase cabine pentru băi.

---

* Comandantul Sanatoriului de Balneofizioterapie şi Recuperare Medicală „Dr. Dimitrie Cantemir” Bălţăteşti

În anul 1883 doctor Konya, autor al analizelor apelor de la Baden-Baden şi de la Slănic Moldova, efectuează cea de-a patra analiză a apelor de Bălţăteşti, constatând că izvoarele de aici „sunt cele mai bogate în săruri din toate apele omologate de pe Continentul European”, comparabile ca nivel cu cele de la: KARLSBAD, MARIENBAD şi VICHY.

Timp de 15 ani doctorul Dimitrie Cantemir a derulat un program masiv de investiții care a avut ca obiective:

- captarea sistematică a izvoarelor,

- realizarea rezervoarelor şi batalurilor pentru depozitarea apei, nămolului,

- construirea clădirilor cu instalațiile necesare pentru funcționarea „Stabilimentului de băi”, a sălii de cură „cu inhalați de brad”, hoteluri şi vile pentru cazare, restaurantul, cazinoul, farmacia, poşta, parcul de brazi şi grădina.

În anul 1930 Stațiunea Bălţăteşti cuprindea:

- Baza de ape minerale cu patru izvoare:

- Izvorul nr. 1 - CAROL,

- Izvorul nr. 2 - INDEPENDENȚA,

- Izvorul nr. 3 - ELISABETA,

- Izvorul nr. 4 - CUZA-VODĂ

- „Hotelul mare” cu 48 camere;

- „Hotelul nou” cu 18 camere;

- „Vila Lili” cu 16 camere;

- „Vilele Cantemir şi Telegraf” cu câte 10 camere;

- „Vila Priveliştea”
-
- „Vila Coleandru”

După decesul doctorului Dimitrie Cantemir, văduva sa se căsătoreşte cu George Eduard Arapu, un moşier din județul Botoşani, care arendează stațiunea pentru zece ani lui Cristian Adolf administratorul moşiei Bălțăteşti.

În perioada 1916-1918 în incinta Băilor, din Ordinul Ministerului de Război, a funcționat Spitalul Militar 171 Buzău.

În anul 1920, George Eduard Arapu vinde Băile, doctorilor Lazăr şi David Goldhamer din Botoşani; aceştia au repus în stare de optimă funcționare baza de tratament şi baza de cazare.

În perioada celui de-al II lea Război Mondial în localul Băilor Bălţăteşti a funcţionat pentru o perioadă scurtă de timp Spitalul de zonă interioară nr. 622.

În baza ordinului nr. 3417 din 17 aprilie 1948, dat de prefectul judeţului Neamţ, comisia Prefecturii, primarul şi notarul comunei Bălţăteşti precum şi şeful Postului de Jandarmi, au preluat prin rechiziţie de la proprietarul David Golhamer „Băile Bălţăteşti".

În perioada 1948-1993 Staţiunea a fost administrată succesiv de către Staţiunea Balneoclimaterică Slănic Moldova şi întreprinderea de Turism Balnear-Baltur, societăţi comerciale care nu au putut susţine şi organiza eficient activitatea staţiunii, fapt ce a determinat Consiliul Judeţean Neamţ ca prin Decizia nr. 23 din 19 mai 1993 să transfere „fără plată" staţiunea în administrarea Ministerului Apărării, pentru o perioadă de cel puţin 15 ani.

Din momentul preluării, Ministerul Apărării prin Direcţia Medicală şi celelalte structuri de specialitate a derulat un program amplu de investiţii, dotare, modernizare, care să pună în valoare toate elementele de balneaţie:

- rezultatele binefăcătoare ale apelor sunt obţinute graţie acţiunii fiziologice a elementelor principale: clorura sodică, săruri sulfuroase, iod, fier cu efecte curative deosebite;
- aerul din regiune foarte bogat în ioni negativi are un efect reconfortant asupra organismului, de sedare şi de tonifiere totodată;
- datorită calităţii deosebite a factorilor naturali de cură, Sanatoriul Bălţăteşti oferă largi posibilităţi terapeutice, încadrându-se ca principala formă de tratament în: poliartrita reumatoidă, spondilita ankilopoetică, discopatii lombare, lombosciatică, spondiloza, coxartroza, gonartroza, artrozele mâinilor şi picioarelor, periartrita scapulo-humerală, osteoporoza, sechele posttraumatice, anexite, sterilitate, frigiditate, paralizii şi pareze, poliomelita, tromboflebita, dermatoze, rinite, sinuzite, astm bronşic, boli endocrine, nevroze, neuroastenii, tulburări de creştere la copii, rahitism.

Având în vedere:

- cadrul legislativ reprezentat de Legea nr. 95/2006 privind reforma în domeniul sănătăţii, Legea nr. 346/2006 privind organizarea şi funcţionarea Ministerului Apărării, Hotărârea Guvernului nr. 442/1992, completată cu Hotărârea Guvernului nr. 1580/2002 privind refacerea capacităţii de muncă a personalului armatei care lucrează în condiţii vătămătoare sau participă la misiuni în sprijinul păcii, în afara graniţelor ţării.
- unicitatea Sanatoriului, dată de starea complexă de mineralizare şi concentraţia apelor minerale, susţinute de gradul de dezvoltare atins de Sanatoriu prin: active, dotare, logistică, personal şi experienţa acumulată în mai bine de 150 de ani de funcţionare, cu performanţe interne şi externe recunoscute, deschid şi consolidează perspectiva dezvoltării viitoare a sanatoriului în cadrul administrativ, creat de Ministerul Apărării în colaborare cu structurile specifice din organica Consiliului Judeţean Neamţ şi în strânsă relaţie cu Agenţia pentru Dezvoltare Regională Nord-Est, existând premisa şi şansa formării unei nişe unice pe piaţa specializată pe recuperări şi reabilitări fizico-psihice, post operaţionale, a eşaloanelor combatante reîntoarse din teatrele de operaţii, precum şi pentru reinserţia profesională şi socială a personalului activ sau în rezervă, beneficiari ai serviciilor de sănătate oferite de Casa Asigurărilor de Sănătate a Apărării Ordinii Publice, Siguranţei Naţionale şi Autorităţii Judecătoreşti;
- resursele balneologice active, cu efecte deosebit de favorabile în tratarea afecţiunilor aparatului locomotor, sistemului nervos, sistemului circulator, respirator, afecţiunilor ginecologice şi a bolilor asociate;
- cadrul natural deosebit, având o atmosfera foarte bogată în ioni negativi, cu efecte reconfortante şi de tonifiere psihomotorie a organismului;
- obiectivele turistice unice în ţară:

■ ***Piatra Neamț*** oraș, reședință a județului cu importante izvoare ale istoriei şi culturii noastre: Muzeul de Ştiințe Naturale, Casa memorială Calistrat Hogaş, Fondul documentar Gh. T. Kirileanu, Bâtca Doamnei (cetate dacică), Curtea Domnească, Biserica şi Turnul cu ceas ctitorite de Ştefan cel Mare (1498-1499), Rezervația paleontologică „Cozla-Pietricica-Cernegura" (Faună fosilă), Căldările uriaşilor (monumente ale naturii).

■ ***Târgu Neamț*** oraş pe malurile râului Ozana, ia poalele Culmii Pleşu, are următoarele obiective: Cetatea Neamț, Muzeul de istorie, Casa Ion Creangă, Casa Veronica Micle, Şcoala Domnească, în imediata vecinătate a oraşului se află stabilimentul balnear al Stațiunii Oglinzi, colecția de artă populară Nicolae Popa din satul Tărpeşti la 10 km.

■ ***Mănăstirea Horaița*** ctitorită în jurul anului 1725 este refăcută la 1867 de arhimandritul Ermoghen Buhuş. În apropiere se află Schitul Horăicioara.

■ ***Mănăstirea Bistrița*** ridicată la 1400 este principală ctitorie şi necropolă a domnitorului Alexandru cel Bun. Mănăstirea Pângărați ridicată în timpul domniei lui Ştefan cel Mare, inițial a fost biserică din lemn. Devine mănăstire după 1560 sub domnitorul Alexandru Lăpuşneanu.

■ ***Mănăstirea Văratec*** fondată în 1785 de maica Olimpiada pe locul unei ctitorii din lemn a lui Ieremia Movilă. Dispune de: colecții de artă veche, mărturii despre oamenii de cultură ce au trecut pe aici - M.Eminescu, Al.Vlahuță, C.Hogaş, M. Sadoveanu, Ionel Teodoreanu; Statuia doamnei Safta Brâncoveanu - 1935 Ion Jalea, locul de veci al Veronicăi Micle, Rezervații naturale „Codrii de aramă" (Dealul Filioru), „ Pădurea de argint" (cu mesteceni de peste 200 ani).

■ ***Mănăstirea Agapia din Vale*** înălțată la 1644 de hatmanul Gavril Coci frate al domnitorului Vasile Lupu. În 1860 Nicolae Grigorescu execută pictura interioară cu tablouri în stil realist şi colorit de valoare deosebită. Aici au creat Bogdan Petriceicu Haşdeu şi fiica sa Iulia, I.L.Caragiale, Al. Vlahuță, G.Coşbuc. În zonă se află şi biserica Agapia din Deal, edificiu al sec. XIV, restaurată de către domnitorii Petru Rareş, Petru Şchiopu şi Duca Vodă.

■ ***Mănăstirea Neamț*** principal complex arhitectonic medieval de cult din Moldova, aparține sec.XIII, este succesiv ctitorită de Petru I Muşat, Alexandru cel Bun şi Ştefan cel Mare.

■ ***Mănăstirea Secu*** înălțată de vornicul Nicolae Ureche la 1602 este o construcție arhitectonică specifică Țării Româneşti, incintă fortificată cu turnuri de apărare.

■ ***Mănăstirea Sihăstria*** aşezământ din jurul anilor 1650 dispune de o biserică nouă, ridicată la 1734 de episcopul Ghedean de Huşi.

■ ***Rezervația Dragoş Vodă*** deține singurele exemplare de zimbri, faună de pădure şi de iaz. Este situată la 2 km sud de Mănăstirea Neamț.

■ ***Bicaz*** cu muzeul de istorie, Hidrocentrala Stejarul şi Portul Lacului Izvorul Muntelui ce asigură curse de agrement. În împrejurimi se pot vizita: Colecția de etnografie şi creație populară şi peştera Toşorog din comuna Bicazu Ardelean. Rezervațiile Cheile Bicazului - monument al naturii, Lacu Roşu (Stațiune Climaterică, lac natural de baraj).

- ■ ***Durău*** staţiune climaterică şi de practicare a sporturilor de iarnă, este situată la poalele versantului nordic al Masivului Ceahlău. Are ca obiective turistice: Schitul Durau pictat între anii 1935-1937, de pictorul Nicolae Tonița care a folosit tehnica encausticii (culori topite în ceară) procedeu antic. Se pot face drumeții până la Vf. Toaca.

Toate acestea reprezintă argumente puternice pentru păstrarea Sanatoriului de Balneofizioterapie şi Recuperare Medicală „Dr. Dimitrie Cantemir" Bălțăteşti în administrarea Ministerului Apărării şi subordinea Direcției Medicale, pentru înființarea Centrului de refacere fizică şi psihică a capacității de muncă a personalului din Sistemul Național de Apărare.

Caracteristicile balneo-climaterice ale stațiunii Bălțătești în recuperarea şi tratamentul tulburării de stres posttraumatic

Col. Conf. Dr. Gheorghe MOSCALIUC[*]
Psiholog Principal Iuliana ZAVADOVSCHI[**]

OBIECTIV: Potențialul balnear al stațiunii Bălțătești prezintă o serie de particularități care o individualizează între celelalte stațiuni balneo-climaterice din țară, oferindu-i un loc special în recuperarea şi tratamentul unor afecțiuni ale aparatului locomotor, afecțiuni neurologice periferice, afecțiuni ale SNC, afecțiuni ORL, afecțiuni cronice ale aparatului respirator, dar şi în cele determinate de tulburările de stres posttraumatic.
MATERIAL ŞI METODĂ: Prezența unor grupe de substanțe terapeutice, ape minerale în conținutul cărora au fost determinate cantități importante de Na, Cl, Mg, Ca, Fe, K, I, acid carbonic şi clorhidric, şi factori climaterici cu acțiune sedativă asupra organismului uman cu o aeroionizare naturală predominant negativă au efecte benefice în diferite afecțiuni, anxietate, depresie, tulburări nevrotice, astm bronşic, hipertensiune arterială, etc.
CONCLUZII: Stațiunea Bălțătești este locul recomandat pentru recuperarea fizică şi psihică a participanților în teatrele de război, fiind un centru în care pot fi tratate atât problemele medicale, cât şi cele specifice.

factori climaterici recuperare tulburare de stres posttraumatic

ABSTRACT
Purpose: Bălțătești, as a balneotherapy place, is marked by several individualities, with recommendation in treatment of locomotion, peripheral and central neurological disorders, ENT disorders, chronically respiratory diseases, as well as for treatment for Post-traumatic stress disorder.
Material and method: The presence of therapeutically substances, mineral waters (dominated by Na, Cl, Mg, Ca, Fe, K, I, carbonic acid and hydrogen cloride), climaterical facts with sedative action, has a benefic action in diseases, anxiety, depresion, nevrotic deseas, bronchial asthma, hypertension, etc.
Conclusion: Bălțătești is recommended for physical and psychical recovery of veterans, where can be treated medical and specific problems.

Key words: climacteric facts, recovery, PTSD

INTRODUCERE

Potențialul balnear al stațiunii Bălțătești prezintă o serie de particularități care le individualizează între celelalte stațiuni balneo-climaterice din țară, şi anume:

- prezența unor grupe de *substanțe terapeutice*;
- *ape minerale* în conținutul cărora au fost determinate în cantități importante sodiu, clor, magneziu, calciu, fier, potasiu, iod, acid carbonic şi clorhidric; de asemenea există Izvorul Nr. 4 (părăsit) a cărui ape erau utilizate pentru cura internă deoarece aveau un conținut mare de sodiu, clor, brom, iod, calciu şi magneziu, apa având un gust sărat-amărui şi o greutate specifică de 1,0148 g;
    - ape iodurate şi clorurate-sodice
    - ape sulfatate cu un conținut de 1 g de sulfat la litru, combinat cu ioni de sodiu, potasiu, magneziu şi calciu;
    - ape minerale sulfatate, care conțin cel puțin 1 g la litrul de apă substanțe solide dizolvate, din care predomină anionul SO_4^{2-};
- *factorii climaterici:* cercetările de bioclimat au permis stabilirea unor corelații între caracteristicile climaterice şi reacțiile fiziologice ale organismului uman.

Cercetările efectuate au arătat că valorile elementelor climatice, moderate tot timpul anului, au acțiune de crutare (sedativ-indiferentă) asupra organismului uman, care nu primeşte stimuli prea intenşi. Numărul mediu de zile cu confort termic, calculat pe baza relației dintre temperatura aerului, umezeală si vânt, în condițiile în care un organism uman sănătos, îmbrăcat uşor, în repaus, nu pierde şi nu primeşte căldură, este în luna iulie, la amiaza, de 9.

---

[*] Clinica ORL, Spitalul Militar Clinic de Urgență „Dr. Iacob Czihac” Iaşi

[**] Clinica de Psihiatrie, Spitalul Militar Clinic de Urgență „Dr. Iacob Czihac” Iaşi

Numărul mediu de zile cu inconfort prin încălzire, tot în luna iulie, la amiaza, este de 7, iar numărul de zile cu inconfort prin răcire variază, în funcție de altitudine, între 5 şi 10. Numărul de zile cu confort prin adăpost de vânt, în luna iulie, la ora 13, este intre 10 si 15. La o viteza a vântului mai mare de 3,5 m/s, organismul uman resimte inconfort, chiar dacă temperatura este cuprinsă în limitele de confort.

Numărul mediu de zile cu inconfort datorat încălzirii prin adăpost de vânt este în luna iulie, la ora 13, între 10 si 13, iar a celor cu inconfort datorat răcirii prin adăpost de vânt este mai redus de 10. Indicele climato-turistic, calculat pe baza relației I=(S+T-5D)/5 dintre durata de strălucire a soarelui pe cer (S), temperatura medie lunară a aerului (T) şi durata precipitațiilor, excluzând precipitațiile din timpul nopții (D), evidențiază luna iulie ca fiind optimă (indice între 50 şi 80) şi pentru băi de aer.

Pe baza cunoaşterii valorilor elementelor climatice în limitele cărora organismul uman prezintă o stare medie de echilibru a sistemelor reglatoare, s-au calculat indicii de stres.

Depăşirea pozitivă sau negativă a valorilor optime determină stimularea sau stresarea organismului, antrenând mecanismele de autoapărare şi de adaptare pentru păstrarea homeostazei interne. Stresul bioclimatic cutanat este determinat de senzațiile de căldură şi de frig pe care le resimte organismul în procesul termoreglării. În cursul anului perioada noiembrie-martie este hiper-tonică, lunile iulie şi august sunt hipotonice, iar perioadele aprilie-iunie şi septembrie-octombrie sunt relaxante. Valoarea medie anuală a indicelui de stres bioclimatic cutanat este redusă (14). Stresul bioclimatic pulmonar se bazează pe schimburile respiratorii prin absorbția de oxigen şi eliminarea de bioxid de carbon. Poate fi determinat în condițiile în care tensiunea vaporilor de apă depăşeşte limitele optime şi acționează asupra mucoaselor căilor respiratorii. În condițiile în care tensiunea vaporilor de apă este cuprinsă între 7,5 şi 11,6 mb, climatul este echilibrat, relaxant, nestresant. Perioada noiembrie-martie, cu tensiunea vaporilor de apă sub 7,4 mb, are caracteristici deshidratante pentru mucoasele căilor respiratorii, iar perioada mai-septembrie este hidratantă, deoarece tensiunea vaporilor de apă depăşeşte 11,7 mb. Lunile aprilie şi octombrie sunt echilibrate.

Cercetările medicale au dovedit influența climatului aeroelectric asupra organismului uman, o aeroionizare naturală, bogată, predominant negativă are efecte benefice, de sedare în diferite afecțiuni: nevroze, astmul bronşic, hipertensiunea arterială, sporind astfel valoarea balneo-medicală a stațiunii.

Electricitatea atmosferei are influențe asupra organismului uman, mai ales prin ionizarea naturală a aerului. Predominarea ionilor pozitivi determină reacții nefavorabile ale organismului uman. Ionii negativi au o influență favorabilă în tratarea astmului bronşic, reumatismului, hipertensiunii, nevrozelor şi surmenajului.

La Bălțăteşti, măsurătorile privind nivelul aeroionizării au înregistrat un număr mediu total de 1055 ioni + şi - / cm^3 aer, din care 560 ioni -/cm^3 şi 495 ioni +/cm^3, coeficientul de unipolaritate fiind de 0,88[9]. Cercetările diferiților geofizicieni din ultimii ani indică o concentrație optimă de radon, care individualizează zona şi măresc efectele benefice ale curei balneare.

Plantele medicinale reprezintă factori naturali de cură foarte răspândiți şi din ce în ce mai solicitați în domeniul balneo-medical (fitoterapie), atât în prepararea unor medicamente, cât şi în cura externă, în băi cu plante. Medicamentele pe bază de plante sunt realizate şi în laboratorul PLANTAVOREL din Piatra Neamț, reprezentând un avantaj în tratament. În consecință, având în vedere tendințele manifestate pe plan internațional şi succesul de care se bucură aceste produse, ele ar putea fi valorificate cu succes la nivelul produselor balneare. Subliniem că existența unor produse secundare de tip extract obținute din ape minerale şi nămoluri, cum este sarea de Bălțăteşti, permite continuarea tratamentului la domiciliu.

Prezența unor substanțe minerale terapeutice, climato-terapia, marea diversitate a plantelor medicinale, amplasarea stațiunii balneare într-un cadru pitoresc, în apropierea unor obiective turistice naturale (Pădurea de fag şi molid de pe Înălțimea cu cota 706, cariera de Piatră), sau antropice, alte obiective turistice (mănăstirile Neamț, Văratec, Agapia, Secu). Fiind o zonă predominant agrară există legume şi fructe de sezon proaspete, localnicii preocupându-se intens să obțină produse ecologice care pot fi valorificate în realizarea unor produse 100% naturale şi servite în cadrul stațiunii.

În prezent Sanatoriul de balneo-fizioterapie şi recuperare medicală este dotat cu instalații moderne pentru electroterapie, afuziuni, duşuri scoțiene, duş-masaj, duş subaqual, saună, aerosoli, tratament ginecologic, sală de cultură fizică medicală şi recuperatorie, bazin de hidrokinetoterapie. Băile cu apă clorosodică caldă sunt completate cu băi galvanice şi împachetări cu nămol de sediment, masaj manual.

MATERIAL ŞI METODĂ

În prezent în stațiunea Bălțăteşti sunt tratate eficient următoarele afecțiuni:

- surmenaj fizic şi intelectual: stări de convalescență; anemii (tip Biermer); copii apatici, rahitici, convalescenți, debili, pulmonari, astenici, cu tulburări de somn, creştere, stări reumatismale, enuresis nocturn, reumatism cronic degenerativ;
- afecțiuni ale aparatului locomotor: afecțiuni reumatismale degenerative şi inflamatorii cronice (spondilita anchilozantă, artropatia psoriazică); afecțiuni discoradiculare (lombosciatică, discopatii lombare, recuperare post hernii de disc operate); artroze (coxatroză, gonartroză, artrozele mâinilor: artroze proximale tip Bouchard, artroze distale tip Heberden; toate stările preartrozice cu diverse localizări); sechele post-traumatice (sechele musculare: atrofii, hipotrofii, contracturi, retracturi; leziuni de nervi periferici; sechele vasculotrofice: tromboflebite, algoneuro-distrofii, limfedem; sechele articulare: redori, anchiloze);
- afecțiuni ginecologice în stări hiporeactive (procese metroanexiale; insuficiențe funcționale minore neuro-endocrine; sterilitate; deviații şi deplasări uterine; dischinezii hipotone; laxitate ligamentară; frigiditate) şi hiper-reactive (tulburări de pubertate şi menopauză; stări de convalescență; metroanexite cronice);
- afecțiuni neurologice periferice (paralizii, polinevrite, sindrom coadă de cal, poliradiculopatii sechelare);
- afecțiuni ale sistemului nervos central (sindrom hemiplegic, sindrom paraplegic);
- afecțiuni cronice ale aparatului respirator;
- afecțiuni asociate: boli vasculare, dermatologice, profesionale, endocrine, respiratorii cronice, ginecologice cronice, digestive cronice şi nevroze.

Apele sulfatate se utilizează în special în cura internă pentru tratarea afecțiunilor digestive şi hepatobiliare, datorită efectelor principale ale acestora: coleretic, colecistokinetic; conținutul de iod din aceste ape adaugă un plus de efecte care lărgesc indicațiile de cură. Astfel, în crenoterapie aportul de iod contribuie la stocarea sa în tiroidă, indicată în afecțiuni endocrine, tiroidiene şi ovariene, la care se adaugă şi efectele congestive şi stimulatoare asupra mucoasei digestive.

Stresul bioclimatic total, care prezintă influența globală a climatului asupra organismului uman, la nivelul pielii şi al plămânilor, este minim (40), caracterizând oraşul ca având un bioclimat sedativ, de cruțare, cu nuanțe de excitare. Acest tip de bioclimat este favorabil persoanelor sănătoase sau cu stări de surmenaj, persoanelor în vârstă sau pentru bolnavii care nu pot suporta căldura excesivă, amplitudinile termice mari sau umezeală mare a aerului.

Este cazul afecțiunilor cardiovasculare, reumatismului poliarticular acut sau al convalescenței de hepatită acută. Bioclimatul cu caracteristici sedative este indicat şi pentru copiii cu stări de nervozitate, fiind lipsit de contraindicații terapeutice, indiferent de sezon.

Datorită acestui bioclimat considerăm că staţiune Bălţăteşti poate fi o destinaţie pentru recuperarea fizică şi psihică a militarilor întorşi din teatrele de război, precum şi a celorlalţi militari.

Creşterea numărului de militari întorşi din teatrele de război care suferă de TSPT ne determină să susţinem necesitatea unei cure balneare şi de recuperare medicală fizică şi psihică.

CONCLUZII

În decursul anilor mulţi pacienţi şi-au găsit vindecarea în tratamentul oferit de această staţiune, ceea ce ne determină să susţinem că alături de recuperarea medicală poate fi făcută şi cea psihică, prin înfiinţarea unui Centru pentru tulburarea de stres posttraumatic adresat militarilor şi personalului civil participant la diverse misiuni. Activitatea centrului ar trebui să fie atât de prevenţie, cât şi de recuperare.

În acest sens propunem:

- pregătirea psihologică timp de 3-4 zile a militarilor selectaţi pentru misiuni, prin conceperea unui program virtual având drept scop transpunerea militarilor selectaţi pentru teatrele de război în faţa situaţiilor în care pot genera tulburarea de stres posttraumatic, petrecând experienţe similare celor stării de război. Prin monitorizarea bătăilor inimii, respiraţiei, transpiraţiei, pot fi urmărite efectele create de starea virtuală care genereazǎ răspunsurile emoţionale ce pot identifica potenţialii militari predispuşi tulburării de stres posttraumatic.

Ideea de bază constă în inducerea de stimuli asemănători stării reale pe o perioadă mare de timp şi încercarea de a păstra răspunsurile psihofiziologice la un nivel cât mai scăzut. Astfel, persoana poate învăţa înainte de misiune, într-un mediu terapeutic securizant, controlul reacţiilor emoţionale pentru ca apoi să exteriorizeze şi să generalizeze în viaţa de zi cu zi din timpul misiunii propriu-zise.

Noutatea acestei propuneri constă în educarea gestionării stresului înainte de misiune, comparativ cu specialiştii de la Centrul Medical Naval din San Diego, unde dr. Dennis Wood aplică acest procedeu după întoarcerea din misiune.

- la revenirea militarilor din teatrele de operaţiuni vor beneficia timp de aproximativ 14 zile, împreună cu familiile, de programe de consiliere şi psihoterapie, individuale şi de cuplu, care se vor centra pe următoarele aspecte:
- antrenarea în managementul anxietăţii generalizate (individual);
- terapie cognitiv-comportamentală de grup prin expunere şi antrenarea abilităţilor sociale;
- terapie de cuplu pentru reintegrarea în familie şi dezvoltarea relaţionării emoţionale şi a comunicării[*];

Simptomele de tulburare de stres posttraumatic pot să apară în primele luni de la revenirea din misiune, de aceea propunem ca toţi militarii să beneficieze şi de consiliere psihologică, concomitent cu recuperarea medicală.

ROLUL INFORMAȚIILOR MEDICALE ŞI PRELUCRAREA LOR ÎN VEDEREA PREGĂTIRII MISIUNII

Maior medic, instructor superior Bogdan SAVU[*]

Rezumat: Lucrarea îşi propune să discute pre-planificarea şi pregătirea asigurării medicale a forțelor aflate în deplasare şi în curs de desfăşurare. Există foarte multe informații/date, dar obiectivul esențial pentru această etapă constă în utilizarea lor cât mai eficientă. Informațiile trebuie să ajungă la momentul potrivit şi să contribuie la conceperea de măsuri care să protejeze populația expusă.

informații medicale asigurare medicală operații de susținere a păcii

ABSTRACT:
There is presented the force medical pre-deployment preparation in Peace Support Operations. There is a lot of information, but the main purpose is how to use it the most efficiently possible. So, the data must be processed in time and measures be established in order to prevent the excessive morbidity and mortality in both the civilians and response personnel.

Key words: Medical Intelligence, Medical Support, Peace Support Operations

Scopul asigurării medicale în Operațiile de Susținere(asigurare) a Păcii este de a îmbunătăți ori, cel puțin, de a menține starea de sănătate a populației. Planificarea adecvată a asigurării medicale a Operațiilor de Susținere a Păcii determină punerea în practică şi folosirea măsurilor de prevenire a morbidității şi mortalității excesive atât în rândurile civililor cât şi la nivelul efectivelor Forței implicate in operațiile de susținere a păcii. Lucrarea îşi propune să discute pre-planificarea şi pregătirea asigurării medicale. Există foarte multe informații/date, dar obiectivul esențial pentru această etapă constă în utilizarea lor cât mai eficientă. Informațiile trebuie să ajungă la momentul potrivit şi să contribuie la conceperea de măsuri care să protejeze populația expusă. Aşadar prezentarea se va axa pe Informațiile Medicale.

În timp ce restul personalului întreține tehnica militară pentru ca armele să fie folosite de mai multe contingente... serviciul medical trebuie să-şi concentreze efortul asupra efectivelor (luptătorilor) ... asupra celor care constituie “arma umană”.
Vor fi abordate:

- cerințele pentru serviciul medical, specifice activității din garnizoana de reşedință,
- evaluarea stării de sănătate şi nivelul individual de pregătire din punct de vedere medical (PIMR),
- cerințele pentru serviciul medical privind perioada anterioară desfăşurării efectivelor,
- controlul medical/activități specifice perioadei anterioare desfăşurării,

---

[*] Institutul Medico-Militar, Bucureşti

- Informaţiile Medicale
- Şedinţele de lucru (informare, punere de acord, luare de decizii) pentru serviciul medical în perioada anterioară desfăşurării efectivelor.

De-a lungul istoriei sunt consemnate multe exemple în care pierderi de personal determinate de îmbolnăviri şi de o activitate neadecvată de protejare a sănătăţii forţelor au influenţat rezultatul operaţiilor militare. Multe dintre ele ar fi putut fi prevenite, iar istoria, cum este ştiută astăzi, ar fi putut arăta altfel.

Situaţia actuală din lume şi noul rol asumat de NATO, mai ales, cel al Forţei NATO de Răspuns (NRF) a complicat în mod evident utilizarea forţelor. Desfăşurarea rapidă este şi va continua să fie cuvântul de ordine. De aceea, cu mai puţine forţe disponibile ca număr, aparţinând tuturor naţiunilor, efectivele vor participa la deplasări mai frecvente şi de mai lungă durată. Pe durata operaţiilor externe există riscul îmbolnăvirii, al influenţelor mediului cu efecte necunoscute, există ameninţările activităţii teroriste şi mereu potenţiala expunere la acţiunea armelor de distrugere în masă.

Iar lista poate continua... Toate aceste posibile riscuri trebuie identificate şi trebuie stabilite măsuri de reducere şi chiar anihilare a impactului lor asupra sănătăţii personalului înainte ca prima unitate să fie desfăşurată. Acesta este obiectul de activitate al segmentului Informaţii Medicale.

În conflictele moderne, mai cu seamă în Operaţiile de Susţinere a Păcii (PSO) majoritatea pierderilor sunt datorate îmbolnăvirilor şi rănilor dobândite altfel decât în luptă (DNBI). De la primul rănit în luptă (WW) până la Desert Storm DNBI rămân cele mai importante. Aşa că este necesar ca acestea să fie studiate în primul rând. Responsabilitatea consilierului pe probleme medicale şi cea a celui care răspunde de planificarea medicală în raport cu Comandantul şi cu Forţa angrenată constă în a se asigura că este conceput şi pus în aplicare un program dinamic şi cuprinzător de protecţie a sănătăţii forţei. Unul dintre segmentele care participă la aceasta este cel al Informaţiilor Medicale.

Care sunt cerinţele segmentului medical, specifice activităţii din garnizoană înainte de deplasare? Efectivele răspund individual de menţinerea stării de sănătate. De exemplu, în cadrul Forţelor Aeriene ale Statelor Unite, fiecare formaţiune/unitate are un medic responsabil cu supravegherea stării de sănătate (Unit Health Monitor). Trupele îşi stabilesc vizitele medicale prin UHM. Acestea includ:

- Controlul preventiv (Preventive Health Assessment -PHA) – adică examinarea medicală şi actualizarea fişei, care trebuie făcute o dată la 12 luni
- Examenul stomatologic – adică examenul stomatologic profilactic şi detartrarea, care trebuie făcute o dată la 12 luni
- Examenul de laborator – testul HIV o dată la 24 de luni, G6PD, DNA, grupa sanguină, alte teste potrivit ordinelor in vigoare
- Vaccinări – fiecare trebuie să fie la curent cu ceea ce este de făcut
- Optometrie – purtătorii de ochelari trebuie să aibă mască de gaze adecvată.

Toate acestea conduc la Estimarea Preventivă a Sănătăţii / a Nivelului Individual de Pregătire din punct de vedere Medical, altfel zis PIMR.

Baza de date PHA(Control Preventiv)/ Nivel Individual de Pregătire din punct de vedere Medical (PIMR) poate fi folosită pentru a urmări nivelul de pregătire din punct de vedere medical al personalului, în totalitate, în vederea deplasării.

Procentul PIMR trebuie să fie foarte ridicat pentru a controla nivelul de pregătire din punct de vedere medical.

Aceste date pot fi postate pe web cu actualizări aproape în timp real; acest sistem este acum disponibil pentru comandanți.

Sistemul care se numeşte METRIC trebuie să fie inclus la nivelul Comandamentului şi al Forței Principale.

Activitățile medicale premergătoare deplasării sunt: revizuirea fişelor medicale individuale pentru ca solicitările de materiale medico-sanitare să fie in conformitate cu acestea; problematica de ordin medical nesoluționată să fie redirijată; evaluarea fiecărui participant la deplasare din punct de vedere medical, stomatologic, psihologic, cu vaccinările la zi; verificarea apartenenței fiecăruia la sistemul (de stat) de asigurare a sănătății; fişa medicală astfel actualizată însoțeşte fiecare participant la deplasare. Medicul care lucrează în cadrul segmentului Informației Medicale este cel care stabileşte imunizările specifice cele mai adecvate (febra galbenă, meningită, JE , variolă, antrax, gripă), prescrie medicația pentru prevenirea malariei dacă este necesar (clorochină, meflochină, doxiciclină).

La recoltarea de sânge un eşantion este dirijat către depozit – aşa încât dacă la testul HIV se constată că cineva este seropozitiv, atunci necesarul de sânge să fie asigurat. Trebuie să existe oportunitatea contactului cu un medic pe probleme de sănătate: sarcină, ochelari, medicație pentru boli cronice.

Definiția **Informațiilor Medicale** conform AFMIC: **IM analizează acea categorie de informații care are în vedere bolile infecțioase şi factorii de mediu care, influențând sănătatea, pot conduce la degradarea eficienței forțelor desfăşurate pe teritorii străine.**

Comitetul Medicilor Şefi ai Serviciilor Medicale ale țărilor membre NATO şi partenere (COMEDS) dă definiția următoare: **MEDINT este produsul prelucrării informațiilor medicale, bio-ştiințifice, ambientale raportate la sănătatea omului şi a animalelor. Această activitate fiind de natură tehnică specifică necesită o competență medicală binecunoscută pentru direcționarea şi prelucrarea datelor pe parcursul ciclului de informare**.

Pe de altă parte, în STANAG NATO 2481 **Informația Medicală constituie orice informație cu privire la amenințările de natură medicală sau de mediu sau la facilități ori capabilități medicale, primită pe alte canale decât cele specifice şi care nu a fost analizată prin prisma Serviciului de Informații.** Asemenea informație constituie o componentă esențială a planificării medicale operaționale şi trebuie făcută cunoscută membrilor Alianței. Acest tip de informație are o valoare potențială imensă pentru analiştii MEDINT, în măsura în care reprezintă o sursă importantă de „adevăruri de bază/inițiale” raportate la domeniul medical.

Elementul cheie este că Informația Medicală nu a fost analizată din punctul de vedere al serviciului de informații pentru a-i constata semnificația.

Cine este funcționarul superior responsabil cu Informația Medicală (MIO)?

Poate fi desemnat un medic ofițer de Sănătate Publică, sau un cadru mediu medical cu experiență în sănătate publică. Funcționarul superior responsabil cu Informațiile Medicale (Medical Intelligence Officer = MIO) trebuie să posede cunoştințe minuțioase de medicină şi fie instruit şi în domeniul medicinii preventive.

Importanţa MIO este mare.

Sursele Serviciului de Informaţii Medicale (un procent de 95% din Informaţia Medicală este disponibil ca SURSĂ DESCHISĂ) sunt, de exemplu, Centrele Statelor Unite pentru Prevenirea şi Controlul Îmbolnăvirilor, Centrul de Informaţii Medicale al Forţelor Armate ale Statelor Unite, Registrul Agenţiei Centrale de Informaţii pentru Evenimente din Lumea Întreagă, Organizaţia Mondială a Sănătăţii, Pro Med Digests, CDC Paginii Aurii, www.weather.com! Şi o sursă cu circuit închis provenind de la Serviciul de Informaţii şi SIPR AFMIC.

Este important de reţinut faptul că **NATO nu adună, analizează ori stochează informaţii de natură medicală pentru naţiunile aliate. Transferul de informaţie medicală în cadrul Alianţei este un rezultat al legăturii dintre parteneri.**

O abordare rapidă a domeniului Informaţiei Medicale presupune ca acesta să fie bine delimitat în ceea ce priveşte o posibilă ameninţare: pericol generat de mediu, de boli infecţioase, de boli contagioase, de igiena muncii, de floră sau faună; după cum pentru riscurile reale trebuie precizate: incidenţa/prevalenţa bolii, morbiditatea/mortalitatea, dacă este boală endemică sau epidemică, factorii de risc, condiţii de apariţie/scenarii şi măsuri de prevenire/combatere; esenţială este găsirea unei modalităţi de a atenua riscul: prin utilizarea echipamentului personal de protecţie, a sistemului de anihilare a vectorilor, prin profilaxie cum este pentru malarie, prin utilizarea repelenţilor, prin vaccinări adecvate, prin corectă hidratare, hrănire, mişcare, respectare a ciclului muncă/odihnă.

Determinantă este prevenirea prin cunoaşterea fenomenului şi a condiţiilor în care se declanşează, iar fără măsuri de combatere este imposibilă gestionarea sa!

Alte probleme de luat în discuţie sunt capabilităţile medicale ale ţării gazdă, informarea cu privire la reptilele veninoase pentru a căror muşcătură sunt necesare antidoturi specifice, precum şi căile aeriene de evacuare disponibile.

Ca exemplu se propune prezentarea activităţii de informare premergătoare desfăşurării trupelor americane în Irak. Toate subiectele abordate până acum sunt de interes permanent şi trebuie reluate pentru actualizare, lunar. Ceea ce trebuie să aibă loc cât mai frecvent posibil sunt instructajele/conferinţele în cadrul cărora se transmite şi se discută informaţia medicală.

Se identifică bolile generate de hrană, cele infecţioase şi cele transmisibile, sistemele de anihilare a vectorilor, stresul de luptă, antidoturile chimice şi biologice, existenţa/nonexistenţa bolilor profesionale, factorii de stres din mediu, animalele, plantele şi insectele periculoase. Se precizează problemele de mediu: temperaturi extreme, peste 130ºF, leziunile provocate de căldură (şocuri calorice, insolaţie, deshidratare) în timpul verii, furtuni frecvente de praf sau nisip, respectarea orarului de activitate şi odihnă şi a hidratării. Senzaţia de sete nu este un bun indicator al nivelului de hidratare. Nu trebuie aşteptat până apare senzaţia de sete pentru a consuma lichide. Este bine să se insiste pentru un consum de 250 ml/oră. Trebuie urmărită cantitatea de urină eliminată, trebuie purtate haine largi şi trebuie aplicat sistemul de îngrijire reciprocă (boddy–boddy).

Discutând despre bolile generate de hrană şi apă, trebuie spus că sistemul imunitar este destul de lipsit de apărare faţă de sursele de îmbolnăvire din hrana din ţările în curs de dezvoltare, apa şi gheaţa trebuind să fie considerate contaminate ca şi hrana şi apa vândute în sistemul economic local (deliberat sau accidental).

Trebuie optat între A LUPTA & A CÂŞTIGA şi A VOMA PÂNĂ LA ULTIMA PICĂTURĂ & A PIERDE.

Se foloseşte numai hrana, apa şi gheaţa provenite din surse aprobate.

Pericolul bolilor transmisibile cum ar fi chlamidia, gonorrhea, HIV poate fi controlat prin folosirea elementelor de protecţie individuale şi cel mai bine, prin abstinenţă. Nu se merge şi nu se înoată în apa rece pentru a evita pericolul generat de schistosomiază. Nu se admit în unităţi animale – mascotă pentru a evita pericolul turbării; se raportează orice muşcătură. Nu se consumă lapte sau produse din lapte nepasteurizat (lapte/brânză de capră).

Febra Q este rezultatul contactului cu oi infectate. Pentru a evita pericolul Antraxului nu trebuie consumată carne provenind din surse neaprobate. Apariţia sindromului Hantaviral este asociat cu excremente de rozătoare, după cum febra hemoragică de Crimeea este asociată expunerii la acarieni/căpuşe. Nici o medicaţie nu protejează împotriva leishmaniozei cauzată de înţepăturile vectorilor. Trebuie purtate uniforme tratate cu permetrin, cu mâneci lungi şi nesuflecate. Trebuie raportată orice leziune care nu se vindecă. Sistemul de anihilare a vectorilor presupune dotarea forţei cu uniforme şi aşternuturi tratate, ori/şi cu produse care se aplică direct pe piele (repelenţi)

.

Iată un exemplu de dotare cu vaccinuri şi medicamente împotriva malariei pentru profilaxia bolilor infecţioase într-un ipotetic teatru de operaţii unde sunt amplasate trupele.

• **Variolă**	**DA**
• **Antrax**	**DA**
• **Febra tifoidă**	**DA**
• **Febra galbenă**	**NU**
• **Meningococ**	**NU**
• **Influenţa**	**DA**

Pentru combaterea ameninţării NBC şi utilizarea corectă a antidoturilor este esenţial ca fiecare participant la misiune să fie corect informat. Igiena muncii urmăreşte modul în care fiecare participant la misiune îşi păstrează echipamentul individual de protecţie.

Activitatea în zona de desfăşurare (teatrul de operaţii) presupune existenţa unor potenţiale pericole pentru sănătate ca, de altfel, şi activitatea din garnizoană.

Condiţii aspre de mediu şi lipsa unei protejări a ochilor au condus la numeroase leziuni ale ochilor în rândul forţelor, mergând până la pierderea vederii. Deci, nu trebuie neglijat portul ochelarilor de protecţie şi al ochelarilor de soare, după caz.

Pericolul contactului cu plante periculoase poate fi evitat prin purtarea uniformei cu mâneci lungi şi nesuflecate şi a mănuşilor, dacă se poate. Se evită contactul mecanic cu cactuşi, cu plante cu tulpini subţiri şi ascuţite, cu buruieni şi bineînţeles nu se ingerează nici măcar de curiozitate.

Dacă în zonă este semnalată prezenţa şerpilor să se reţină că sunt mai activi în perioada mai rece din zi. Orice muşcătură de şarpe trebuie raportată imediat.

Contactul cu artropodele trebuie evitat. Prezenţa păianjenilor, a miriapodelor, a scorpionilor poate duce la înţepături dureroase şi potenţial periculoase. Orice înţepătură se aduce la cunoştinţa personalului medical. Dimineaţa se scutură hainele şi încălţămintea pentru a evita surprizele neplăcute.

Stresul de luptă, chiar fără a intra în detalii trebuie luat în consideraţie.

În concluzie

MENȚINEREA STĂRII DE SĂNĂTATE A FORȚEI ÎN GARNIZOANĂ +

Pe la anul 400 î.c., Hypocrates din Cos, un medic şi profesor de medicină, grec de origine, afirma:

„ Trebuie prevăzute efectele anotimpurilor; dacă se studiază vântul, căldura, frigul, calitatea apei şi terenul unei zone ... se pot şti bolile care există, cum pot fi tratate acestea şi, ceea ce este cel mai important, cum să se prevină apariția lor.”

Cât am învățat cu adevărat în 2407 ani ?!!

Obiectivul informatizării unei biblioteci

Pcc Bibliotecar Cristina ŞCHIOPU[*]

Abstract
Informatica are avantajul de a reface rapid căile de comunicaţie atunci când beneficiază de programe specializate de abordare a datelor ierarhizate astfel încât să se acceseze prin mijloace la îndemâna cititorului informaţii cu caracter de ansamblu sau specializate.

---

digitalizare organizarea informaţiei bază de date index program reţea pagină de prezentare

Noile sisteme de informare informatizate; instrumentele de informare tipărite: cataloage, bibliografii, lucrări de referinţă precum şi recomandările directe ale personalului specializat; împreună cu programe diverse de activităţi legate de carte şi documentul cu valoare ştiinţifică şi culturală aduce biblioteca în dialog cu cititorul.

Proiectarea unei baze de date începe cu decizia privind numărul şi tipurile de tabele pe care le va conţine baza de date.

Proiectarea şi crearea unei baze personalizate ţine cont de următoarele criterii:

- Utilizare şi dotare tehnică
- Ansamblul funcţiilor prelucrării de date
- Convivialitate
- Ergonomie
- Reţele
- Posibilităţi de întreţinere
- Asistare pentru diferite probleme
- Demonstraţii

Definiţii

Server: Calculatoare de mare putere, situate în general la distanţă, care satisfac cererile de prelucrare ale unor utilizatori.

Username:

Nume logic care desemnează un utilizator de sistem sau de bază de date, asociat în general la o parolă la momentul conectării.

Interesul unei biblioteci se manifesta pentru:

- suporturi noi, digitalizarea documentelor păstrate în bibliotecă
- interesul utilizării de documente electronice în bibliotecă: păstrare, consultare, asigurarea de documente înlocuitoare
- problemele juridice sau consultare pe loc.

Organizare şi planificare informaţională în slujba societăţii:

- Analiza situaţiei existente:
- Dezvoltarea structurii

---

[*] Spitalul Clinic de Urgenţă Militar Central Dr. “Carol Davila” e-mail: crisqbun@yahoo.com

Posibila organizare a strategiei de informatizare:

1. Procedurile de prelucrare, circuitul documentelor;
2. Relațiile dintre cei care prelucrează documentele
3. Regulile de prelucrare
4. Organizarea pe fişiere, descrierea prelucrării intrare/ieşire
5. Relații – entități de lucru (indexuri)
6. Îmbunătățirea existentului pe baza obiectivă a probelor
7. Încadrarea în normele de funcționare (rapoarte de gestiune)
8. Metode de eliminare din stoc. Suport web
9. Baza de date şi achizițiile bibliotecii
10. Concluzii

Organizarea bazelor de date

Planul de aplicație şi metoda de lucru

- ordinea de introducere a datelor
- timpii de aşteptare
- cititorii

1. Proceduri conform circuitului datelor

Datele contabile (specifice evidenței de bibliotecă: data cererii de ofertă / prețurile; data facturării / plății; data introducere contabilitate; data BPTR; data introducerii în evidențele de bibliotecă)

Introducerea datelor la timp (decalajul de timp necesar circuitului documentelor)

2. Datele de gestiune. Schimbul de informații

Bazele de date au fost structurate după ce s-a stabilit dacă şi în ce măsură pe parcursul studiului intervine necesitatea schimbului de informații.

Colecțiile bibliotecii cuprind date din următoarele domenii:

- Medicina internă
- Hematologie
- Laborator şi Farmacie
- Oftalmologie
- Neurologie, Neurochirurgie
- Psihiatrie
- Dermatologie
- Histologie şi Atlase
- Homeopatie
- Pediatrie
- Stomatologie
- O R L
- Ginecologie
- Urologie
- Chirurgie
- Traumatologie
- Cardiologie
- Medicină sportivă
- Reumatologie
- Pneumologie
- Chirurgie toracică
- Radiologie şi imagistică
- Biografii

Gestiunea înregistrărilor programate (succesiunea etapelor pentru fiecare sector de evidență) .

3. Regulile de prelucrare

Introducerea datelor la timp

Datele de împrumut (nume, adresa, telefon)

Baza de date cu evidenta cititorilor

Datele privind cititorii, condiţiile şi regimul de împrumut

Gestiunea listelor cu cititori (datele de împrumut / restituire – ştergerea din evidenţă)

Baza de date a bibliotecii.

4. Organizarea pe fişiere

Prin număr şi indici (set de litere), bazele de date vor stabili tipul de date bibliografice pe care le va accesa personalul:

- Bibliotecă cu caracter ştiinţific, informaţional organizaţional şi economic
- Bibliotecă de documentare ştiinţifică cadre medii
- Bibliotecă cu caracter şcolar
- Bibliotecă cu caracter umanist (ştiinţe universale şi literatură)
- Bibliotecă cu caracter ştiinţific de cercetare.

5. Relaţii conform indexurilor

Analiza şi documentarea bazelor de date

6. Probe. Reactualizare

7. Raportări de gestiune

În multe cazuri, un raport răspunde la întrebări importante despre conţinutul bazei de date.

Pe lângă furnizarea de informaţii detaliative şi rezumative, care pot include calcule (câmpuri cu valoare calculată) ca în punctual 5, rapoartele au şi următoarele caracteristici:

- Raport uşor de citit şi de înţeles
- Anteturi şi subsoluri care tipăresc informaţii de identificare în partea de sus a fiecărei pagini
- Gruparea şi sortarea care organizează informaţiile

1.Date contabile (conturi contabile; solduri)

2.Date de gestiune (lucrul cu evidenţele)

3.Reguli de prelucrare

Conform etapelor de introducere stabilite

Sintaxa

Tools – Analize – Documentar

4. Proiectarea de tabele

Stocarea datelor într-o bază de date

Problemele de clasificare.

Problemele de "traseu" a unei cărţi de la înregistrare la împrumut şi la restituire.

Relaţionări

Verificări automate periodic prin condiţii de lansare în execuţie la Conectare automată (SQL analyzer)

Consultarea informaţiilor pe suport web (PHP)

Adaptate pentru structura noastră.

5. Filtrarea datelor

Prin combinarea clauzelor where. Where filtrează anterior grupării datelor, în timp ce Having filtrează după această operaţie, ceea ce reprezintă o diferenţă importantă.

Securitatea bazelor de date

Constrângerile reprezintă o componentă importantă a aplicării integrităţii referenţiale; indexurile putând contribui la îmbunătăţirea performenţelor operaţiei de prelucrări ante sau post-execuţie, iar opţiunile de securitate se pot folosi pentru gestiunea accesului la date.

Indexare. Sortare

Un index din Access este o structură de date invizibilă care stochează ordinea de sortare a unui tabel pe baza câmpului indexat, programul Access consultă indexul şi este capabil să sorteze tabelul foarte rapid.

După indexarea unui câmp, se pot vizualiza şi apoi modifica indexurile după cum este necesar.

Printre operațiile care sunt frecvent securizate se numără următoarele:

- Accesul la caracteristicile de administrare a bazelor de date (crearea tabelelor, modificarea sau ştergerea tabelelor existente etc.)
- Accesul la anumite baze de date sau tabele
- Tipul de acces (numai pentru citire, acces la anumite coloane etc.)
- Accesul la tabele numai prin intermediul descris al vederilor sau al procedurilor stocate
- Crearea unor niveluri multiple de securitate, permițând diferite niveluri de acces şi control, bazate pe conectarea la sistem
- Limitarea capacității de gestionare a conturilor de utilizator.

Salvarea datelor pe un suport extern contribuie la întreținerea datelor în format electronic.

Suporturile materiale de salvare sunt dischetele, CD şi micromemoriile (buffer) indicate pentru volum mare de date stocate.

9. Baza de date şi achizițiile bibliotecii

Se poate interoga baza de date pentru a stabili în ce măsură următoarea achiziție completează structura tehnică sau informația teoretică a domeniului pe care s-a prezentat raportul.

Astfel se stabilesc echivalențe şi efecte directe / indirecte asupra deciziilor referitoare la organizarea analitica a datelor.

Scopul strategiei de informatizare este să faciliteze definirea:

- Statutului administrativ al bibliotecii
- Autoritatea de decizie
- Publicul de deservire
- Locul său într-o rețea
- Mediul său informatic

10. Concluzii. Repartizări.

Trebuie să fii bibliotecar şi abia apoi să admiți cărțile şi internetul ca viață umanizată.

PAGINI DIN ISTORIA MEDICINII MILITARE ROMÂNEŞTI

Mărturii ale activității serviciului sanitar român în timpul Campaniei din Vest (1944-1945)

Mr. medic Elena Ramona POPA[*]

OBIECTIV: prezentarea unor documente de luptă ce dovedesc activitatea serviciului sanitar al Armatei 4-a române în timpul Campaniei din Vest (1944-1945) ;
DISCUȚII: Campania din Vest cuprinzând operațiunile militare duse de trupele româneşti pentru eliberarea Ardealului de Nord, a Ungariei şi a Cehoslovaciei de sub ocupația germană a însemnat pentru serviciul sanitar român eforturi susținute pentru menținerea efectivelor luptătoare în condițiile grele de război şi ale iernii anului 1944/1945 dar şi activități de ajutorare a populației civile din zonele respective amenințate şi de pericolul tifosului exantematic .
CONCLUZII: personalul medical şi sanitar inferior al Armatei 4- române, prin eforturi proprii, a contribuit la menținerea efectivelor combatante, mulți dintre medici şi sanitari pierzându-şi viața în timpul luptelor din cadrul Campaniei din Vest (1944-1945) ;

documente de luptă serviciul sanitar Campania din Vest

PURPOSE: presention of some war's documents that define the activity of the medical service of the 4-th's romanian Army during the West Campaign (1944-1945);
DISCUSSION: The West Campaign including the military operations done by romanians troups for gaining the freedom of North Ardeal, Hungary and Cehoslovacia from the german occupation, meant a difficult task for the romanian military medical service, due by the very hard winter of the 1944's but also because of the necessary activities for helping civilian people and because of the epidemy of typhos.
CONCLUSION: the medical staff of the 4-th's romanian Army, with their own meanings, sustained the health of the military forces, and many of them lost their life during the West Campaing.(1944-1945)

Răsfoind recenta lucrare „Jurnal de front - Armata a 4-a română în Campania din Vest (1944-1945)" a căror autori sunt general-maior dr. Ioan Ciupei şi colonel (r.) dr. Vasile Tutula, lucrare apărută la Editura Cluj Napoca în 2006 aflăm lucruri deosebite cu privire la activitatea serviciului sanitar român în perioada 5 septembrie 1944-12 mai 1945. Autorii şi-au concentrat eforturile asupra prezentării unor documente inedite aflate în arhivele militare referitoare la Campania din Vest, campanie ce a cuprins operațiile militare duse de către armata română pentru eliberarea Ardealului de Nord, a Ungariei şi Cehoslovaciei de sub ocupația germană.

Campania din Vest a fost „ o campanie care a durat 246 zile, atacând timp de 203 zile şi alte 137 de nopți de atac sau deplasări tactice pentru înlocuiri în dispozitiv". Nu a fost o campanie uşoară, au subliniat autorii lucrării, au fost condiții de luptă specifice; marşurile s-au desfăşurat în majoritatea cazurilor pe jos, pe timp de iarnă; în Cehoslovacia, zăpada fiind de 1-1,5 m cu troieni şi viscole mari, terenul a fost în majoritate muntos, la altitudini de 800-1500 metri; temperaturi ce s-au menținut continuu la minus 20 grade. Pierderile umane au fost mari, aproximativ 90.000 de militari români.

Prezentăm 2 documente ce ilustrează emoționant câteva aspecte ale activității sanitare desfăşurate de către medicii şi sanitarii români:

---

[*] Unitatea Militară 01110 Str. Dr.Vicol nr. 2 Iaşi

Documentul nr.1
„Divizia 9 Infanterie
Comandantul

Ordin de Zi nr.71
Din 16 mai 1945

În grelele lupte pe care divizia le-a purtat în Ardeal, Ungaria şi Cehoslovacia, Ambulanța Militară nr.81 condusă de medicul căpitan dr. Menaide Ioan, funcționând în toate ocaziile cât mai aproape de linia de luptă şi desfăşurând o activitate neobosită şi-a adus reale şi neprețuite servicii frontului.

Aşa, în luptele de la Mureş (Ungheni, Cristeşti, Sântioara, etc) deşi încadrată numai cu doi medici a ridicat, operat, pansat şi evacuat în timp de 5 zile, printr-un efort supraomenesc, peste 1500 răniți făcându-şi un punct de onoare de a nu lăsa nici un rănit fără ajutor, în ciuda obstacolelor ce păreau de netrecut.

Mai târziu, organizându-se şi încadrându-se cu personal şi mijloacele necesare chiar pe câmpul de luptă, această formațiune aduce aportul unui adevărat spital în care răniții noştri găsesc dragostea camaraderească şi desăvârşită pricepere medicală îmbinate printr-o fericită împrejurare într-un deosebit elan al împlinirii datoriei.

Medicul căpitan dr. Menaide Ioan, el însuşi exemplu , în mijlocul subalternilor, înconjurat de o echipă de medici tineri, dar pricepuți şi pătrunşi de frumusețea misiunii pentru care au fost chemați aici, mereu prezenți la datorie, muncind ziua şi noaptea şi îmbărbătând răniții din grelele lupte de la Tisa, Megzaszo, Valea Hernadului, Perin, Jablonica, Brezno, Valea Hronului, Banska Bystrica, Valea Vahului etc, au reuşit prin curajoase şi pricepute intervenții chirurgicale să dea ajutorul necesar la peste 6500 răniți şi bolnavi dintre care 800 au fost tratați pe loc şi înapoiați frontului, iar restul puşi în situația de a suporta în cele mai bune condițiuni şi fără risc evacuarea către formațiunile sanitare dinapoi.

În toată această activitate, trupa sanitară a ambulanței, bine instruită şi bine condusă, a fost la înălțimea misiunii sale. Brancardierii acestei formațiuni, adânc pătrunşi de datoria lor şi disprețuind primejdia au dat ajutorul atât de necesar, chiar în linia de foc, sub ploaia de gloanțe şi obuze, plătind uneori cu viața.

Ajutorul medical a fost dublat şi de o deosebită atenție pentru curățenia, hrana şi cazarea răniților şi bolnavilor, fapt ce a determinat pe toți şefii ierarhici ca în desele inspecții ce au făcut să nu aibă decât cuvinte de laudă pentru comandantul, ofițerii şi trupa ambulanței, medicul şef al Armatei 4 calificând-o drept o formațiune ce face fală armatei.

Pentru conştiinciozitatea, curajul, spiritul de sacrificiu, priceperea şi munca neobosită puse în slujba celei mai nobile misiuni, redresarea fizică şi morală a răniților, pentru deosebit de frumoasele rezultate obținute,

ordon:

Citarea prin ordin de divizie a medicului căpitan dr. Menaide Ioan, medicul şef al Ambulanței Sanitare nr.81, precum şi a ofițerilor, subofițerilor şi trupei acestei formațiuni de serviciu, spre a-i servi ca exemplu în împlinirea datoriei în cel mai nobil înțeles al cuvântului.

Dat la Cartierul general al Diviziei 6 Infanterie, în Kadov (Moravia) la 18 mai 1945.

Comandantul Diviziei 6 Infanterie
General I. DIMULESCU

Arh.M.Ap.N., fond 4,dosar nr.82, f 118, **Copie** “

Documentul nr.2

„Ambulanţa 81-a Sanitară
Oficiul poştal Militar nr.54

Nr.5561
Din 18 mai 1945

Către

Divizia a 6 a Infanterie
Stat Major, Biroul 1

La ordinul Dvs.,nr.2410 din 16 mai 1945;

Am onoare a vă raporta următoarele :

Ambulanţa 81 Sanitară a căutat în toate împrejurările, indiferent de localitate şi naţionalitate, să vină în ajutorul populaţiei civile lipsită de asistenţă medicală şi de imposibilitate de a se trata din cauza condiţiilor şi distrugerilor grave ale războiului.

Ajutorul medical a fost dat neprecupeţit tuturor cetăţenilor care l-au cerut, deseori dându-se consultaţii gratuite şi asistenţă medicală necesară chiar la domiciliul cetăţenilor bolnavi netransportabili administrându-li-se în nenumărate cazuri unde era absolută nevoie şi erau în imposibilitate de a şi le procura, medicamentele necesare.

Se adaugă la aceste numeroase consultaţii şi distribuire de medicamente, facerea a numeroase pansamente civililor răniţi ca şi câtorva mari operaţii făcute pentru maladii care cereau imediata intervenţie chirurgicală, punând în caz contrar viaţa lor în pericol.

La această bogată asistenţă medicală care va fi ilustrată mai jos cu multiple cazuri, ambulanţa a contribuit deseori cu mijloacele sale proprii, să evacueze la Spitalele de Campanie româneşti, numeroşi răniţi civili, hrăniţi şi întreţinuţi în ambulanţa până la evacuare.

S-a contribuit de asemenea la prevenirea maladiilor contagioase din sate şi la stăvilirea epidemiilor, luându-se măsuri de izolare şi de parazitare a contagioşilor acolo unde au fost găsiţi.

Am ajutat de asemenea cu câteva căruţe la evacuarea civililor din comuna Kraşidobrocs, ajutând în acest fel la păstrarea bunurilor cetăţenilor:

Ca exemplu acum pentru asistenţa medicală acordată ostaşilor citām:

În Ungaria

În comuna Foro şi în comuna Garadna s-au dat consultaţii şi s-au făcut pansamente la 7 civili bolnavi şi răniţi din explozie de focos. În comuna Geci-Bator a fost operată o femeie dezarticulându-i-se degetul mare al piciorului stâng, cangrenat în urma unei plăgi de război.

A fost tratată de asemenea o apendicită acută cu plastron, care periclita viaţa bolnavei. Au fost vizitaţi şi patru civili cărora li s-au dat medicamentele necesare iar un grav rănit a fost pansat şi îngrijit în ambulanţă.

În comuna Percupa au fost consultaţi 3 civili, dându-li-se medicamentele necesare.

În Cehoslovacia

În comuna Dobrocs, unde ambulanţa a stat o lună de zile, s-a dat o bogată asistenţă medicală la civilii răniţi şi la bolnavii din întreaga regiune cetăţenii venind zilnic în număr mare la consultaţii. S-au dat peste 120 consultaţii medicale, făcându-se numeroase pansamente şi câteva mari operaţii.

Ilustrez cu cazurile mai importante:

1. Un copil din comuna Ianoşova cu un mare flegmon difuz al antebraţului drept, care punea întreg membrul superior în pericol, iar viaţa îi era ameninţată, a fost operat şi tratat până la vindecare în ambulanţă.

2. O fată de 20 ani rănită, cu fractura gambei drepte, fiind în pericol grav viaţa mamei şi a copilului, I s-a făcut o operaţie cezariană salvându-se copilul.
3. O familie întreagă din comună, compusă din 6 persoane rănită prin explozia unei grenade, a fost mult timp îngrijită în ambulanţă.
4. O femeie bolnavă grav de cord, a fost de asemenea tratată .
5. Bolnavi gravi de pleurezie, alţii cu tulburări gastro-intestinale, furunculoze, arsuri, etc. au fost trataţi.
6. S-au făcut numeroase extracţii dentare. În plus s-au dat numeroase consultaţii medicale, împărţindu-li-se şi medicamente la sugari, dându-li-se sfaturi pentru îngrijirea lor.
7. În comuna Poniki s-au dat peste 10 consultaţii şi s-au făcut pansamente la civili răniţi şi bolnavi.
8. A fost operată şi scăpată de la o moarte sigură o femeie din aceeaşi comună, cu o cangrenă umedă la gamba piciorului stâng după o plagă de război.
9. De asemenea un civil partizan cu o zdrobire a gambei drepte prin explozie de mină a fost operat făcându-i-se apoi multiple seruri şi transfuzii de plasmă salvându-l de la moarte.
10. Tot în această comună s-au luat măsuri pentru izolarea şi deparazitarea civililor la care se iviseră cazuri de boli contagioase.
11. În comuna Stranz au fost pansaţi şi îngrijiţi peste 10 răniţi veniţi din comuna Salkova, Sinita, etc. cu plăgi grave de război şi apoi evacuaţi cu maşina la spitalele româneşti din Nove Mesto.
12. Un băiat de 18 ani rănit grav prin explozie de mină cu o zdrobire a gambei stângi a fost salvat de la moarte prin operaţie şi transfuzii multiple de seruri şi plasmă.
13. În comuna Zaharoviţe, au fost operaţi şi îngrijiţi medical peste 15 răniţi civili şi apoi evacuaţi o parte la spitalele româneşti.

În concluzie: Ambulanţa 81 Sanitară, ori de câte ori a avut posibilitatea să dea un ajutor sub orice formă şi mai ales medical populaţiei civile a făcut-o, neţinând seamă de naţionalitate şi căutând cât a putut să îmbunătăţească suferinţa cetăţenilor.

Medic şef al Ambulanţei 81 Sanitară
Medic căpitan
/ss/Dr.Menaide Ioan”

Aceste documente arată doar câteva aspecte din activitatea serviciului Ambulanţei 81 Sanitare, parte a serviciului sanitar al trupelor române implicate în Campania din Vest (1944-1945)

BIBLIOGRAFIE

1. IOAN CIUPEI, VASILE TUTULA – *Armata a 4-a română în Campania din Vest (1944-1945)* - Ed. MEGA Cluj-Napoca, 2006 ;

ISTORICUL SPITALULUI MILITAR CRAIOVA

Comandantul Spitalului Clinic de Urgenţă Militar
„Dr. Ştefan Odobleja” – Craiova
Col. dr. Cornel TIŢA

Serviciul sanitar militar s-a născut odată cu primele formaţiuni militare organizate de către Generalul Kiseleff în principate, „Miliţia Românească” în Muntenia şi „Straja pământească” în Moldova.

Existenţa în oraşul Craiova, încă de la început, a unei garnizoane militare puternice, a impus organizarea unei asistenţe medicale autonome pentru militari, cadre şi familiile lor.

Spitalul Militar Craiova datează din anul 1882 prin transformarea fostei Infirmerii Colentina – înfiinţată în anul 1838, pe timpul domnitorului Bibescu Vodă. Ca urmare a obţinerii Independenţei naţionale, în anul 1883, armata română se reorganizează formându-se 4 (patru) corpuri de armată, iar numărul diviziilor se dublează. Spitalele din Craiova, Galaţi şi Iaşi s-au transformat în „spitale de corp de armată”, denumire care a datat până în anul 1927, când se schimbă denumirea în SPITALUL MILITAR CRAIOVA.

Corpul 1 Armată, cu reşedinţa în oraşul Craiova, cuprindea unităţi militare de pe raza fostelor judeţe Mehedinţi, Romanaţi, Dolj, Olt, Vâlcea, Argeş şi Gorj.

Serviciul sanitar al Corpului 1 Armată avea sub ordinele sale în afară de Spitalul de corp de armată din oraşul Craiova – încadrat cu toate secţiile – şi spitalele divizionare din Turnu Severin, Slatina şi Piteşti..

Terenul actual pe care se află Spitalul Militar Craiova, a devenit proprietatea Ministerului de Război în anul 1881, prin cumpărarea acestuia de la doamna Maria M. POENARU – actul nr. 677 – şi de la comuna Craiova – prin actul nr. 571.

În decursul anilor, pavilioanele din cadrul spitalului, au fost construite astfel :

- fostul pavilion administrativ – A – în anul 1893
- pavilionul B1 ORL şi Oftalmologie – pe atunci serviciul chirurgie – în anul 1885 şi restaurat după incendiu în anul 1892
- fostul pavilion B Boli interne în anul 1895 – demolat în anul 1991
- pavilionul B2 Boli contagioase şi actuala spălătorie a garnizoanei în anul 1885
- fostul pavilion farmacie, laborator, policlinică, triaj în anul 1895, sub denumirea de „Pavilionul D” şi ocupat de Depozitul sanitar al Corpului 1 Armată – demolat în 1991
- pavilionul G, în care este instalat punctul de control a fost construit în anul 1893, iniţial având destinaţia de capelă
- castelul de apă a fost construit în anul 1865
- în anul 1996 se dă în folosinţă pavilionul D1, administrativ şi policlinică, în care funcţionează şi secţia Radiologie şi farmacia spitalului.
- pavilionul ocupat în prezent de secţiile Dermato-venerice şi Neuropsihiatrie la etaj şi blocul alimentar la parter, a fost construit în anii 1952-1953.

În anul 1921, se înfiinţează serviciul de radiologie, dentistică şi laboratorul de bacteriologie. În acelaşi an se ocupă şi clădirea Companiei 1 sanitare şi funcţionează în acest pavilion serviciile ORL, Oftalmologie şi Dermato-venerice. Această clădire, după toate probabilitățile, era vechiul local al Infirmeriei Colentina – actualul pavilion B4 în care funcționează secția Chirurgie.

Serviciul Dermato-Venerice

Pavilionul Chirurgie

Împrejmuirea spitalului a fost realizată în anul 1886, instalația interioară de apă în anul 1889 odată cu a întregului cartier, numit atunci „Bariera Caracal”.

Între anii 1953 – 1962 s-au modernizat toate pavilioanele prin compartimentări în saloane mici şi rezerve, iar în anul 1965 se introduce încălzirea centrală, se construiesc alei asfaltate, se aduc o serie de îmbunătățiri la blocul alimentar, baie, spălătorie, se reamenajează serviciul de radiologie, stomatologie şi triaj, precum ți îmbunătățiri substanțiale în ceea ce priveşte dotarea materială cu mobilier, aparatură şi instrumentar sanitar, în toate serviciile medicale.

Perioada 1965 – 1970 este perioada în care spitalul a fost dotat cu aparatură medicală nouă, modernă, de mare tehnicitate.

Între anii 1930 – 1931 apar în cadrul spitalului primii subofițeri droghişti, iar în 1934 se angajează primele infirmiere. Până atunci atribuțiunile personalului mediu sanitar erau îndeplinite de subofițeri sanitari şi sanitari-brancardieri, recruți şi instruiți din rândul militarilor în termen.

În timpul celui de-al doilea război mondial, Spitalul Militar Craiova, a funcționat în actualul local până în primăvara anului 1944, când a fost bombardat şi mutat în cazarma „Alion” unde a funcționat până în anul 1945.

Până în anul 1949 Spitalul Clinic de Urgență Militar „Dr. Ştefan Odobleja” – Craiova a fost subordonat Companiei I-a sanitare din punct de vedere administrativ şi Corpului 1 Armată, din punct de vedere operativ.

Începând din anul 1950 Spitalul Clinic de Urgență Militar „Dr. Ştefan Odobleja” – Craiova devine organ de dotare şi mobilizare luând asupra sa o serie de responsabilități şi obligații privind unitățile teritoriale din regiunea Oltenia.

În decursul anilor au depus o activitate medico-militară susținută personalități de seamă în medicina românească, eminenți profesionişti şi organizatori de sănătate, printre care : general de brigadă doctor Potârcă Iacob, maior doctor Vercescu, primul autor al procedeului operator în hemoroizi, colonel doctor Gheorghe Ioan – medic primar ORL, căpitan doctor Mihăilescu Păunel – medic ORL, colonel doctor Vasilescu Mihai – medic chirurg, colonel doctor Panea Aurel – medic internist, colonel doctor Becherescu Nicolae – medic radiolog, maior farm. Mogoş Ştefan, locotenent colonel medic Ionescu Marcel, locotenent colonel medic Ionescu Mihai, locotenent colonel medic Vasilescu Ion şi mulți alții.

La conducerea Spitalul Clinic de Urgență Militar „Dr. Ştefan Odobleja” – Craiova s-au succedat următorii şefi (comandanți) de spital :

- 1875 – 1883 locotenent colonel doctor Vlasta
- 1883 – 1884 colonel doctor Vercescu Mihai
- 1885 – 1900 locotenent colonel doctor Caligari
- 1900 – 1903 colonel doctor Dumitrescu
- 1903 – 1905 colonel doctor Petrescu Grigore
- 1905 – 1906 colonel doctor Papilan Gheorghe
- 1906 – 1910 colonel doctor Condemin Nicolae
- 1910 – 1913 colonel doctor Antoniu Ilie
- 1913 – 1916 colonel doctor Potârcă Ion
- 1916 – 1917 colonel doctor Elian Ion
- 1917 – 1918 colonel doctor Grueascu M.

Personalul medical al Spitalului Militar Craiova 1920 - 1922

- 1918 – 1920 colonel doctor Ionescu Carp
- 1920 – 1921 colonel medic Baculescu Marin
- 1921 – 1922 colonel doctor Urdărescu M.
- 1922 – 1933 colonel medic Dobrinescu Ioan
- 1933 – 1937 locotenent colonel doctor Panea Aurel
- 1938 locotenent colonel doctor Sărdărescu Ioan
- 1939 – 1940 colonel medic Bălan Ion
- 1940 – 1941 colonel doctor Becherescu Nicolae
- 1942 locotenent colonel doctor Mitran Ilie
- 1943 – 1944 colonel doctor Oprean Gheorghe
- 1945 – 1946 colonel doctor Căpruciu Gheorghe
- 1946 colonel doctor Gheorghe Ioan
- 1946 – 1949 colonel doctor Hucan Constantin
- 1949 – 1953 colonel doctor Ştefănescu Ioan
- 1953 – 1954 colonel doctor Sava Vasile
- 1954 – 1955 colonel doctor Morărescu Aurel
- 1955 – 1958 colonel medic Popovici Radu
- 1958 – 1959 locotenent colonel medic Buzatov Petre

- 1959 – 1962 locotenent colonel medic Vlad Florian
- 1962 – 1968 locotenent colonel doctor Sporea A.
- 1968 – 1984 locotenent colonel medic Lupaşcu Victor
- 1984 – 1985 colonel doctor Predescu Constantin
- 1985 – 1991 colonel doctor Păun Nicolae
- 1991 – 1998 colonel doctor Dumitrescu Ion
- 1998 – 2005 colonel doctor Cheiță Nicolae

Începând cu anul 1968 prin efortul întregului personal, au fost obținute următoarele realizări :

- amenajarea drumului de acces din spital
- mutarea, amenajarea şi dotarea secției radiologie
- construirea şi mutarea secției triaj într-un local corespunzător
- construirea a două bordeie betonate
- amenajarea unui bordei carburanți
- amenajarea parcului auto
- extinderea serviciului stomatologic şi laborator
- construirea de trotuare la pavilionul policlinicii triaj
- reparații capitale şi reamenajarea blocului alimentar
- realizarea unui gard din prefabricate în latura estică a spitalului – 350 m.
- înfrumusețarea parcului spitalului prin plantări de pomi şi arbuşti ornamentali
- amenajarea unei baze sportive
- modernizarea băii spitalului.

Deşi împrejurările au fost dificile, spitalul şi-a asigurat ritmul activ şi a progresat sub diferite aspecte, că era bine încadrat cu personal medical, sanitar – în special corpul subofițerilor – şi administrativ.

Activitatea ştiințifică poate fi considerată sub aspect progresiv. Întreg personalul medical al spitalului şi al garnizoanei contribuie la susținerea activității cercului medico-militar local.

În timpul evenimentelor din decembrie 1989 obiectivul principal l-a constituit apărarea spitalului, evitarea evenimentelor grave , funcționarea spitalului în condițiile în care o parte din secții au fost scoase din funcțiune.

Pavilionul chirurgical avariat la Revolu\ia din Decembrie 1989

După 1990, în cadrul Spitalului Militar Craiova s-au realizat :

- redistribuirea unor spații de spitalizare şi tratament ambulatoriu pentru eficientizarea activității medicale
- s-au îmbunătățit condițiile de spitalizare a pacienților ținând cont de sarcinile spitalului privind asigurarea unui număr mare de unități militare teritoriale

- asigurarea funcţionării Dispensarului Policlinic Militar Caracal
- organizarea de manifestări ştiinţifice de prestigiu
- creşterea prestigiului profesional al spitalului prin impunerea instituţiei ca unitate spitalicească de prestigiu, prin profesionalismul cadrelor militare medicale şi sanitare şi a personalului civil.

În anul 1991 s-a demolat pavilionul B – Boli interne – şi s-a început construcţia actualului pavilion D, iar în perioada 1992 – 1996 s-a construit şi dat în funcţiune pavilionul D în care îşi desfăşoară activitatea Ambulatoriul de specialitate şi Serviciul Administrativ.

Serviciul Boili Interne

Sediul nou al Ambulatoriului de specialitate şi birourilor administrative

Din anul 1998 spitalul intră în relaţie contractuală cu CASAOPSNAJ asigurând servicii medicale şi investigaţii de specialitate de înaltă performanţă pentru personalul Ministerului Apărării Naţionale, Administraţiei şi Internelor, de Justiţie precum şi populaţiei civile din judeţele Dolj, Olt, Vâlcea, Gorj şi Mehedinţi .

După anul 2000 spitalul a fost dotat cu aparatură modernă - ecografe ,holter TA, fibrobronhoscop, laparoscop, aparatură pentru analize de laborator, iar în 2001 a fost s-a pus în funcţiune computerul tomograf .

TOMOGRAFIE COMPUTERIZATA
2002 10 2

Laboratorul de tomografie computerizata

Procesul de reorganizare al armatei a afectat şi Spitalul Militar Craiova reducându-se un număr mare de funcţii militare.

În continuare s-au reamenajat şi modernizat următoarele pavilioane :

- pavilionul B1 ocupat în prezent de secţia Boli Interne

- pavilionul B3 ocupat în prezent de secția Psihiatrie şi compartimentele Neurologie şi Dermato-venerice
- pavilionul C ocupat de Laboratorul de analize clinice prin crearea şi modernizarea spațiilor pentru realizarea circuitelor funcționale
- a fost refăcută împrejmuirea spitalului şi mutat parcul auto
- au fost amenajate spații de depozitare şi a fost renovat depozitul de alimente.

Începând cu anul 2005 spitalul a primit denumirea de Spitalul Clinic de Urgență Militar „Dr. Ştefan Odobleja” .

Dr. Ştefan Odobleja
1902 - 1978

Din anul 2006 a fost pus în funcțiune un nou pavilion în care îşi desfăşoară activitatea compartimentele ORL, Oftalmologie, Unitatea de primiri urgențe şi Serviciul internări-externări.

INSTRUCȚIUNI PENTRU AUTORI

Revista de Medicină Militară este o publicație de prestigiu, cu o vechime de peste 100 de ani. În scopul integrării revistei în circuitul internațional al publicațiilor științifice, autorii sunt rugați să respecte „*Cerințele uniforme pentru manuscrisele trimise jurnalelor biomedicale*” (stilul Vancouver de prezentare) (vezi: New England Journal of Medicine 1991, 324 : 424 – 428; British Medical Journal, 1991, 302; Romanian Jurnal of Gastroenterology 1992, 1/4, 1996, 5/1).

Revista de Medicină Militară este creditată de Colegiul Medicilor din România ca publicație științifică (2,5 credite pentru abonament), creditarea autorilor făcându-se la solicitarea acestora după prezentarea reprintului obținut ca dovadă a editării lucrării (solicitările vor fi adresate personal de autori Colegiului Medicilor din România – Bulevardul Timişoara nr. 15, sector 6, Bucureşti).

TRIMITEREA MANUSCRISELOR

Manuscrisele vor fi trimise redacției pe adresa: *Revista de Medicină Militară* – Direcția Mediclă, Str.Institutul Medico-Militar Nr. 3-5 sector 1, Bucureşti, tel. 021.319.60.06.

Manuscrisele vor fi însoțite de o scrisoare în care se menționează poziția şi calificarea tuturor autorilor, semnată de toți autorii şi conținând următoarele declarații:

1. Lucrarea este originală, nu a mai fost acceptată pentru publicare, nu este în prezent în considerarea vreunei alte reviste pentru publicare şi nu va fi publicată în altă parte fără permisiunea redacției.

2. În cazul articolelor cu mai mulți autori, trebuie menționat că toți au contribuit în mod direct la programarea, executarea sau analiza lucrării raportate, sau la redactarea acesteia. Autorii sunt rugați să facă aceste declarații cu multă grijă şi responsabilitate. Publicarea precedentă sub formă de rezumat trebuie, de asemenea, menționată.

Studiile pe pacienți umani sau studiile experimentale trebuie să respecte reglementările internaționale de etică. Sursele de finanțare sau suportul financiar trebuie menționat cu mulțumirile de rigoare.

În caz de litigiu este util ca autorii să menționeze numele şi adresa a doi experți pe care îi consideră recomandabili pentru a evalua manuscrisul respectiv.

Lucrările vor fi examinate de către doi revizori de specialitate din comitetul editorial. Dacă opiniile lor diferă, articolul este analizat de un alt revizor. Evaluarea articolelor se face în mod anonim, fără ca revizorii să cunoască numele autorilor lucrării.

Comitetul editorial poate solicita autorilor să modifice manuscrisul, în funcție de recomandările revizorilor. Comitetul editorial are dreptul să editeze (modifice) manuscrisele.

Autorii au întreaga responsabilitate pentru conținutul științific al lucrărilor lor.

Articolele care nu sunt conforme cu stilul revistei, sunt returnate autorilor fără a fi analizate de comitetul editorial.

Timpul de editare va fi cât de scurt posibil, în funcție de necesitățile științifice şi editoriale ale revistei.

Manuscrisele trimise spre publicare nu pot fi returnate. Când se primeşte un manuscris, autorii vor fi informați în scris, într-un interval de cinci-şase săptămâni, cu privire la acceptarea, nevoia de revizuire sau respingerea articolului.

Lucrările publicate vor deveni proprietatea revistei.

După publicare, primul autor va primi zece reprinturi ale articolului, în mod gratuit, pentru a fi distribuite celorlalți autori.

FORMATUL MANUSCRISULUI

Manuscrisul trebuie redactat în conformitate cu „*Cerințele uniforme pentru manuscrisele trimise jurnalelor biomedicale*” (stilul Vancouver de prezentare) (vezi New

England Journal of Medicine 1991, 324 : 424 – 428; British Medical Jurnal of Gastroenterology 1992,1/4, 1996, 5/1).

Articolele se redactează în Microsoft Word, Normal+Justf., Times New Roman, Font Size – 16 Bold pentru titlu, Font Size – 12 pentru text, iar rezumatul Font Size – 10 Bold. Pagina trebuie setată din Page setup la 2cm. marginile, format letter.

Autorii sunt rugați să trimită articolul pe dischetă şi două exemplare listate de manuscris (inclusiv pentru tabele şi figuri), rezumatul fiind scris atât în limba română, cât şi în engleză, pe adresa Redacției, tipărite pe o singură față a hârtiei A4, la un rând (inclusiv pentru tabele şi referințe bibliografice), cu margini largi. Pentru textul editat în limba română vă rugăm utilizați setarea de limbă („*Romanian”*) pentru tastatură (în „*Control Panel* ”din *Windows*) şi să nu utilizați alte tipuri de caractere româneşti. **Nu trimiteți manuscrisul în limba română fără caracterele specifice româneşti** (diacritice). Toate paginile trebuie numerotate consecutiv, începând cu pagina de titlu, jos pe centrul paginii.

MANUSCRISUL VA FI PREGĂTIT ASTFEL:

1. PAGINĂ DE TITLU

- Titlul lucrării (nu mai mult de 100 de caractere cu spații), fără abrevieri;
- Prenumele, inițiala celui de al doilea prenume, numele de familie al autorilor
- Numele complet al locului de muncă (instituție şi departament) pentru fiecare autor;
- Adresa de corespondență (cu detalii: grade ştiințifice didactice şi militare, persoana de legătură, telefon, fax, e-mail etc.)

2. PAGINĂ DE REZUMAT

- Rezumatul trebuie să aibă 150, până la 250 de cuvinte şi să cuprindă: obiectivul studiului, material şi metodă, rezultatele fără interpretarea datelor şi concluzii.
- Cuvintele-cheie: 3-4 cuvinte-cheie, după *Index Medicus.*

3. ARTICOLUL PROPRIU-ZIS

a. **Articol original** – cel mult 800-1000 de cuvinte (4 pagini).

b. **Prezentare caz** – cel mult 600-800 de cuvinte (2 pagini)..

c. **Referat general** – cel mult 2.000 de cuvinte (10 pagini).

- **INTRODUCERE**: prezentarea problemei, plasarea în context, scopul şi obiectivele studiului, ipoteza de lucru.
- **MATERIALE ŞI METODE**: pacienți, procedee, echipament (inclusiv indicații cu privire la producător), metoda de lucru, analiză statistică, tehnici operatorii, medicamente etc. (în funcție de specificul articolului), toate acestea fiind descrise în detalii suficient de amănunțite pentru a permite reproducerea studiului de către alți investigatori. În tot textul trebuie folosite aceleaşi nume pentru produse (cu specificarea numelui de marcă între paranteze la prima utilizare). Nu se recomandă numele pacienților.
- **REZULTATE**: fără interpretări.
- **DISCUȚII**: 1 – analiza rezultatelor prin prisma obiectivelor propuse ale studiului cu comentarii cu privire la aspectele lămurite (pozitive sau negative) sau nelămurite prin acest studiu;

2 – comparație între rezultatele obținute de autori şi alte studii din literatură, cu explicații, eventual ipoteze cu privire la diferențele observate, accentuând asupra progresului pe care cercetarea de față îl aduce;

3 – comentarii privind importanța studiului de față, precum şi o punere la punct a situației actuale a subiectului investigat atât în literatură, cât şi în practică; eventual se vor prezenta aici cele mai importante studii sau aspecte din domeniu.

4 – probleme nerezolvate, întrebări la care nu s-a răspuns şi care rămân deschise în viitor pentru studiile ce vor urma, eventuale direcții propuse pentru investigare în domeniul respectiv.

CONCLUZII

La nevoie, aceste capitole mari pot fi împărțite în subcapitole, după necesități.

Se recomandă utilizarea precaută a abrevierilor şi menţionarea numelui complet la prima apariţie în

text a abrevierii respective. Toate referinţele bibliografice vor fi citate în text cu cifre arabe, la exponent, fără paranteze, în ordinea apariţiei (de exemplu: Un alt studiu^{18} arată...). Toate figurile şi tabelele trebuie să fie citate în text în locul în care ele să apară (exemplu: Fig. 3, Tab. 2). Datele care apar în tabele, legendele tabelelor şi figurilor trebuie să fie rezumate, nu duplicate în text.

4. TABELELE

Tabelele trebuie să fie procesate la două rânduri, pe o pagină separată, numerotate consecutiv (cu referire în text în locul unde ele trebuie să apară) şi cu un titlu (exemplu: **Tabelul 1**. Distribuţia pe vârste şi sex a pacienţilor). Capetele de tabel se scriu cu caractere *italice.* Nu trimiteţi fotografii sau imagini ale tabelelor. Utilizaţi tasta „Tab” pentru a separa coloanele (nu bara de spaţiu) şi utilizaţi tasta „Enter” la terminarea liniei. Toate căsuţele goale din tabel trebuie să aibă o liniuţă. Dacă este nevoie, pentru cuvintele sau frazele lungi din căsuţe se vor utiliza abrevieri, însă cu explicarea acestora în subsolul tabelului. Asiguraţi-vă că toate tabelele sunt citate în text.

5. FIGURILE

Toate figurile (ilustraţiile), fie fotografii, diagrame sau grafice, trebuie să fie de calitate. Ele trebuie să fie numerotate în ordinea apariţiei în text (cu referire în text la numărul figurii în locul în care aceasta ar trebui să apară) şi, să poarte un titlu (exemplu: **Figura 1.** Distribuţia pe vârste şi sexe a pacientelor).

Pe această pagină referitoare la figuri, se va face o listă a tuturor numelor figurilor, în ordine numerică (la nevoie, cu legende explicative; identificaţi, în această legendă, orice literă sau săgeată utilizată pe figură).

Toate figurile trebuie să aibă o etichetă pe spatele lor, care să conţină numele figurii, numele primului autor şi o săgeată care indică marginea de sus a imaginii. Nu scrieţi direct pe dosul fotografiilor. Nu îndoiţi, nu ştergeţi, nu lipiţi, nu prindeţi cu agrafe şi nu mototoliţi ilustraţiile. Fotografiile preparatelor histologice trebuie să aibă menţionate mărimea şi coloraţia. Ilustratele preluate din alte publicaţii trebuie să fie însoţite de permisiunea autorului. Ilustraţiile color nu pot fi reproduse color decât pe cheltuiala autorului.

PAGINA DE BIBLIOGRAFIE

Referinţele bibliografice trebuie numerotate consecutiv, în ordinea în care ele sunt menţionate pentru prima oară în text şi se vor redacta cu Font Size – 10. Asiguraţi-vă că aţi identificat toate referirile bibliografice în text, tabelele sau legendele tabelelor ori figurilor prin cifre arabe scrise la exponent (exemplu: Un alt studiu^{18} arată...). Numele prescurtate ale jurnalelor sunt cele conforme cu *Index Medicus.* Pentru articolele obişnuite de jurnale medicale, veţi menţiona toţi autorii atunci când sunt şase sau mai puţini. Atunci când sunt mai mulţi de şase veţi menţiona trei, urmaţi de et al. Stilul în care vă rugăm să faceţi referirile bibliografice rezultă din exemplul de mai jos. Pentru articole din reviste:

1. Blann D.W., Prien S. D.: *Estemation of fetal....*, Am J of Obst and Gynec, 2000, 182 (5): 1117-1120.

ATENŢIE: Referinţele bibliografice vor fi proporţionale ca număr cu mărimea articolului.

ANUNȚ ABONAMENTE

ROMÂNIA
MINISTERUL APĂRĂRII
DIRECȚIA MEDICALĂ A MINISTERULUI APĂRĂRII
ASOCIAȚIA MEDICILOR ŞI FARMACIŞTILOR MILITARI

Revista de Medicină Militară
Direcția Medicală a Ministerului Apărării
Str. Institutul Medico - Militar, Nr.3-5, Bucureşti, sector 1, cod 010919

Abonamentul la **REVISTA DE MEDICINĂ MILITARĂ** pentru anul 2007 este de 25 RON exemplarul/trimestru.

Un abonament anual costă 100 RON (4 x 25 RON).

Abonamentele se vor face pentru toate cele 4 numere ale revistei şi la depunerea banilor în contul de mai jos se va specifica: abonament la RMM/2007.

Pentru abonare se va proceda astfel: sumele se vor depune în contul Asociației Medicilor şi Farmaciştilor Militari din România:

RO52ARBL200000101314RO01
ANGLO-ROMANIAN BANK LIMITED, Bucureşti.

Codul fiscal al AMFMR este: **18375607**

După virarea banilor, **se vor trimite adrese la redacția Revistei de Medicină Militară** în care se va specifica numărul de abonamente, anexându-se obligatoriu în copie şi documentul care să ateste virarea banilor în contul de mai sus (chitanță F 16, ordin sau dispoziție de plată).

Frecvența anodonțiilor parțiale la copiii din Oltenia

Dr. Anne-Marie RAUTEN*, dr. Petra ŞURLIN*,
mr (r) conf. univ. dr. Veronica MERCUŢ*,
dr. Catrinel GEORGESCU*, dr. Matei CUŢUI*

OBIECTIV: Determinarea frecvenței anodonțiilor la pacienții prezentând anomalii dentomaxilare, care au solicitat un tratament ortodontic.
MATERIAL ŞI METODĂ: Studiul a fost efectuat pe 1232 de pacienți, cu anomalii dentomaxilare, care s-au prezentat în Clinica de Ortodonție-Pedodonție a Facultății de Medicină Dentară a UMF din Craiova, între 2001 şi 2007. Au fost efectuate examene clinice şi radiologice.
REZULTATE: Din numărul total de pacienți studiați, 208 au prezentat unul sau mai mulți dinți lipsă. Din cele 208 cazuri de anodonții, în 152 de cazuri a fost afectată doar o grupă dentară, În 52 de cazuri au fost afectate cel puțin două grupe dentare diferite.
CONCLUZII: Incidența anodonției la lotul studiat a fost ridicată, iar forma cel mai frecvent întâlnită a fost anodonția bilaterală de premolari doi inferiori. Adresabilitatea către serviciul de ortodonție s-a făcut pentru anomaliile dentomaxilare asociate. În cazul anodonțiilor de premolari, diagnosticul a fost pus frecvent întâmplător cu ocazia examenului clinic şi radiologic efectuat la debutul tratamentului ortodontic.

anomalii dentomaxilare **anodonție parțială** **tratament ortodontic**

ABSTRACT
Objective: to determine the frequency of the anodonties in patients having dent maxillary anomalies, that solicited an orthodontic treatment.
Material and methods: the study was realized on 1232 patients that were present in Orthodontics-Paedodontics Clinic of Oral Medicine Faculty of Pharmaceutics and Medicine University in Craiova, between 2001 and 2007. The diagnostic was determined on clinical and radiological examinations.
Results: 208 of the cases presented one or more numerical deficiency of dents. In 152 cases was affected only a dental group, and in 52 cases – at least two different dental groups.
Conclusions: the incidence of anodontia was high, and the frequent was presented bilateral anodontia of inferior premolar two. The patients were solicited the orthodontics treatment for associate dent maxillary anomalies. In the anodonties of premolars, the diagnostic was determined accidentally on clinical and radiological examinations in start of the orthodontic treatment.
Key words: dent maxillary anomalies, partial anodontia, orthodontic treatment

INTRODUCERE

Absența unuia sau a mai multor dinți de pe arcada dentară, mergând până la lipsa totală a acestora, datorită neformării mugurilor dentari, este cunoscută în literatura de specialitate sub denumirea de anodonție.

De fapt terminologia utilizată pentru această anomalie dentară izolată este foarte variată, cei mai utilizați termeni fiind: agenezie, anodonție, aplazie, hipodonție, oligodonție, reducere numerică a dinților. După Stockton (1) termenii de hipodonție şi oligodonție desemnează de fapt două entități patologice diferite:

− hipodonția se referă la absența a mai puțin de 6 dinți de pe arcadă,
− oligodonția se referă la absența a mai mult de 6 dinți de pe arcadă.

Frecvența relativă a anodonțiilor, comparativ cu alte anomalii dentomaxilare diferă în literatura de specialitate fiind de: 3,5%-8% în funcție de rasă, dacă se exclud molarii trei, iar dacă se includ şi

---

[*] Facultatea de Medicină Dentară, UMF, Craiova.

aceştia de 15%-25% după Dermaut (2) şi Gulzow (3). Arte şi colab. (4) găsesc o incidenţă de 5% a anodonţiei de incisivi laterali la populaţia europeană, iar Shapira (5) o proporţie de 77% la pacienţii cu despicături labio-maxilo-palatine. La noi în ţară Ionescu Ecaterina găseşte pentru anodonţii o incidenţă de 3,53% (6), iar Ţărmure Viorica de 8,03 % (7).

Prezenţa acestei anomalii are consecinţe negative asupra funcţiilor aparatului dento-maxilar, asupra fizionomiei, fonaţiei, masticaţiei şi determină tulburări de ocluzie (6), întârzieri în erupţia dinţilor învecinaţi (8), putând conduce astfel la complexe de inferioritate şi dificultăţi în încadrarea psihosocială a acestor pacienţi.

OBIECTIVE

Generale:

1. Determinarea frecvenţei anodonţiilor la pacienţii prezentând anomalii dentomaxilare, care au solicitat un tratament ortodontic.

Specifice:

1. Determinarea frecvenţei anodonţiei în funcţie de sex.
2. Determinarea frecvenţei anodonţiei în funcţie de maxilarul afectat.
3. Determinarea ordinului de frecvenţă în funcţie de tipul dintelui afectat.
4. Determinarea numărului total de dinţi absenţi/pacient.

MATERIAL ŞI METODĂ

Studiul a inclus toţi pacienţii prezentând anomalii dentomaxilare, care s-au prezentat în Clinica de Ortodonţie-Pedodonţie a Facultăţii de Medicină Dentară a UMF din Craiova în perioada 2001-2007, solicitând tratament de specialitate, adică un număr total de 1232 pacienţi. Fiecărui pacient i s-a întocmit o foaie de observaţie. Diagnosticul de anodonţie a fost pus pe baza datelor anamnestice culese de la pacient şi/sau aparţinători, pe baza examenului clinic, atrăgându-ne atenţia situaţiile în care lipseau de pe arcadă dinţi permanenţi după limita superioară de erupţie a acestora, concomitent cu existenţa unui proces alveolar pensat în regiunea respectivă sau cu existenţa unui dinte omonim nanic. Ulterior, diagnosticul a fost confirmat radiologic pe ortopantomograme.

REZULTATE ŞI DISCUŢII

Din numărul total de pacienţi studiaţi, 208 au prezentat unul sau mai mulţi dinţi lipsă, iar dintre aceştia 92 au avut doar anodonţie de molari trei, ceea ce conduce la o proporţie de 9,41% pacienţi cu anodonţie (excluzând molarii trei) şi respectiv 16,07% (incluzându-i şi pe aceştia). Incidenţa găsită de noi este asemănătoare cu cea raportată de Haavikko de 9,5% (9) şi de Bergstrom de 9,3% (10).

Distribuţia procentuală pe sexe este prezentată în tabelul de mai jos:

TABEL 1. Distribuţia pe sexe

SEX	FEMININ	MASCULIN
NR. DE PACIENŢI	116	92
FRECVENŢĂ	55,76%	44,24%

Mai afectate sunt fetele, ceea ce corespunde datelor din literatura de specialitate (10, 11, 12).

Distribuţia procentuală în funcţie de maxilarul afectat este prezentată în următor:

TABEL 2. Distribuţia în funcţie de maxilarul afectat

MAXILAR AFECTAT	MAXILAR SUPERIOR	MANDIBULĂ	AMBELE MAXILARE
NR DE PACIENŢI	69	77	62
FRECVENŢĂ	33,14%	37,01%	29,85%

Din cele 208 cazuri de anodonții, în 152 de cazuri a fost afectată doar o grupă dentară, procentele obținute fiind prezentate în următorul tabel:

TABEL 3. Frecvența în cazul afectării unei singure grupe dentare

DINTE ABSENT	NR.CAZURI	FRECVENȚĂ
IC inf.	4	2,63%
IL sup.	12	7,88%
PM 2 sup.	5	3,28%
PM 2 inf.	39	25,66%
M 3 sup.	52	34,21%
M3 inf.	40	26,34%

Dinții cei mai afectați au fost M3 superiori, urmați de M3 inferiori, PM2 inferiori, IL superiori, PM2 superiori şi IC superiori.

În 52 de cazuri au fost afectate cel puțin două grupe dentare diferite.

Din punct de vedere topografic anodonția de premolari doi inferiori a fost bilaterală în 69,24% dintre cazuri şi unilaterală în 30,76% dintre cazuri; cea de premolari doi superiori a fost bilaterală în 60% dintre cazuri şi unilaterală în 40%; anodonția de incisivi laterali a fost bilaterală în 58,33% dintre cazuri şi unilaterală în 41,66%.

Anodonțiile parțiale întinse găsite (puține numeric) au fost asimetrice.

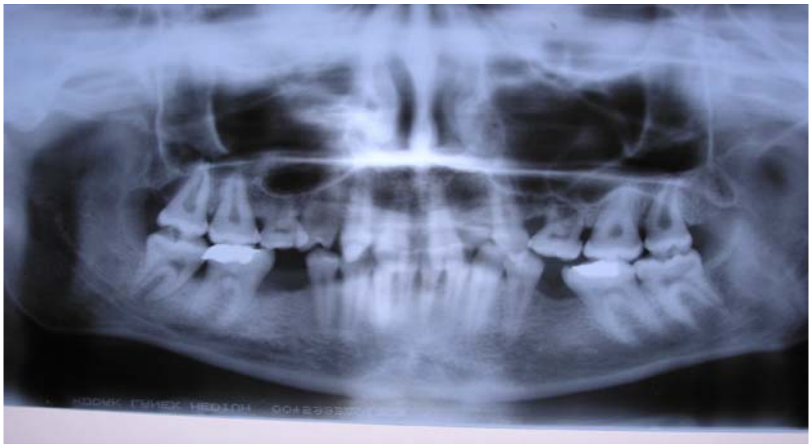

Fig. 1. Pacienta ML, 19ani, prezentând anodonție bilaterală de IL sup, PM1sup stg, bilaterală de PM2 sup, bilaterală de M1 sup, bilaterală de PM2 inf şi M1 inf

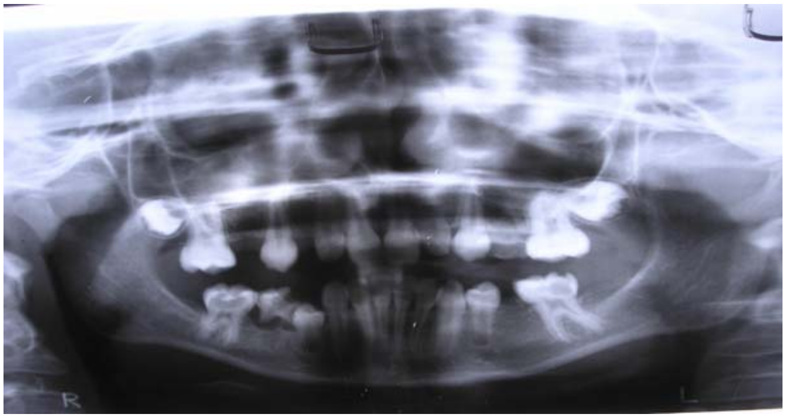

Fig. 2. Pacienta FA, 13 ani, prezentând anodonție bilaterală de M3 sup, a celor patru PMsup şi anodonții bilaterale inferioare de PM2, M2 şi M3.

Distribuţia procentuală în funcţie de numărul de dinţi afectaţi este prezentată în tabelul de mai jos:

TABEL 4. Distribuţia în funcţie de numarul de dinti afectaţi

NR. DINŢI ABSENŢI	NR.CAZURI	FRECVENŢĂ
1	61	29,32%
2	97	46,63%
3	16	7,69%
4	29	13,94%
5	2	0,88%
8	1	0,48%
11	1	0,48%
12	1	0,48%

Se constată că în majoritatea cazurilor sunt afectaţi unul sau doi dinţi.

CONCLUZII

1. Incidenţa anodonţiei la lotul studiat a fost ridicată, dacă nu luăm în calcul molarii trei, şi apropiată de limita inferioară a valorilor menţionate în literatura de specialitate dacă se includ şi aceştia.
2. Forma cel mai frecvent întâlnită, excluzând molarii trei, a fost anodonţia bilaterală de premolari doi inferiori.
3. Exceptând cazurile cu anodonţii parţiale întinse şi o parte dintre cele cu anodonţie de incisivi laterali superiori, adresabilitatea către serviciul de ortodonţie s-a făcut pentru anomaliile dentomaxilare asociate.
4. În cazul anodonţiilor de premolari, diagnosticul a fost pus frecvent întâmplător cu ocazia examenului clinic şi radiologic efectuat la debutul tratamentului ortodontic.

HERNIE PARADUODENALĂ STÂNGĂ CU EVOLUȚIE PARTICULARĂ

Dr.V.BÂTCĂ[*], O.ALBIȚA, O.SIMA,
T.ROGIN , T.BÂTCĂ[**]

Hernia paraduodenală este o afecțiune rară, fiind citate în literatură circa 400 cazuri de la începutul secolului XX. Afecțiunea este dificil de diagnosticat , fiind descoperită întîmplător, cu ocazia unor complicații de natură ocluzivă. În etiopatogenia bolii este implicat procesul de malrotație intestinală, din perioada embrionară, cu apariția fosetelor paraduodenale patologice care generează herniile paraduodenale a căror evoluție poate fi grevată de apariția sindroamelor ocluzive. Este prezentat cazul unei paciente de 36 ani cu sindrom dureros trenant de etaj abdominal superior, etichetat inițial ca ulcer duodenal cronic acutizat, apoi ca pancreatită acută și în ultimă instanță ca un sindrom ocluziv înalt. Se intervine chirurgical confirmîndu-se diagnosticul de hernie paraduodenală stîngă strangulată, descoperindu-se anse intestinale subțiri cu modificări morfopatologice majore. S-a practicat degajarea anselor și desființarea spațiilor herniare prin burse etajate. Nu a fost necesară rezecția de intestin, ansa fiind la limita viabilității. Evoluția postoperatorie este dificilă, instalîndu-se un sindrom mixt de insuficiență hepatică cu coagulopatie și hemoragie digestivă difuză care au pus în pericol viața pacientei. Terapia intensivă complexă aplicată a dus în cele din urmă la o evoluție favorabilă. Raritatea afecțiunii, dificultățile de diagnostic precum și evoluția particulară, ne-au determinat să prezentăm acest caz.

hernie internă paraduodenală fosetă Landzert ocluzie

Paraduodenal hernia is a rare situation, less than 400 cases being published in literature. This condition is difficult to explore, diagnose appear within an occlusive syndrome. The ethiopathoplogy involves perturbation of intestinal rotation during the intrauterine life, producing paraduodenal fosses, which generates conditions for internal hernias and occlusive situations. We present 36 years women with a chronic epigastric pain, diagnosed as duodenal ulcer, later as acute pancreatitis and in the and as high occlusion syndrome. Open laparotomy is performed, discovering a strangulated left paraduodenal hernia, with severe morfopathological lesions of the intestinal loops. Kelotomy and purestring suture of parietal defect is performed. Postoperatory evolution has been difficult with a hepatic failure with coagulopathy and diffuse intestinal hemorrhage, threating the patient life. Intensive care leads eventually at a favorable condition. The rarity of this disease, difficulty to diagnose and the particular evolution are motives to present this case.

INTRODUCERE

Herniile interne au o incidență de 1-2% , ele fiind descoperite întîmplător cu ocazia unor laparotomii sau autopsii sau pot fi cauza unor complicații obstructive ale intestinului în 0,2-0,9% din cazurile de ocluzii intestinale.(1) Herniile paraduodenale reprezintă circa jumătate din herniile interne, entități clinice rare și dificil de diagnosticat.

Hernia paraduodenală are o etiologie congenitală, datorîndu-se unei erori în procesul de rotație al intestinului. Acesta are loc între săptămînile 5 și 10 ale vieții intrauterine datorită unei discordanțe între volumul anselor și capacitatea abdominală a embrionului, intestinele suferă o rotație antiorară de 270° precum și o fuzionare a peritoneului de fascia posterioară a trunchiului. În funcție de poziția duodenului și de orientarea deschiderii fosei paraduodenale se descriu henii paradudenale stîngi sau drepte.

---

[*] Clinica Chirurgie Spitalul Clinic de Urgență Militar Central ”Carol Davila” București
[**] Student anul VI - Universitatea de Medicină și Farmacie ”Carol Davila” București

Cele stîngi sînt cele mai frecvente(75%) şi se presupune că se formează printr-un defect congenital al mezocolonului. Ansele intestinale se angajează într-un spaţiu denumit foseta Landzert, situat în stînga porţiunii a patra a duodenului, delimitată de ligamentul Treitz şi arcul vascular al lui Treitz, cu extensia sacului herniar retrogastric şi prepancreatic.(fig.1)

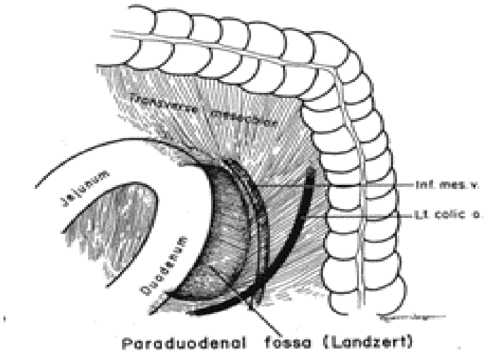

Fig.1 – localizarea orificiului herniar paraduodenal stîng

Herniile paraduodenale drepte se formează prin foseta Waldeyer, sacul herniar fiind delimitat anterior şi la stînga de vena colică dreaptă şi se complică în 50% din cazuri cu obstrucţia parţială sau totală a intestinului.(2)(3).

În literatura medicală s-au prezentat de la începutul sec.XX circa 400 de cazuri, din a căror analiză s-au evidenţiat următoarele concluzii : raportul M/F este de 3/1, vîrsta medie de diagnostic este de 38,5 ani, majoritatea cazurilor prezentîndu-se pentru suferinţă dispeptică cronică dar şi pentru complicaţii acute ce sugerau un sindrom ocluziv înalt.(4)(5)(6)(7)(8)(9)

Deoarece în cea mai mare parte din cazuri hernierea este intermitentă, diagnosticul este foarte dificil de stabilit, necesitând un grad înalt de susceptibilitate pentru coroborarea datelor clinice cu explorările imagistice. Examenul clinic nu evidenţiază niciun fel de modificări specifice, necesitând explorări radiologice(proba Pansdorf) şi tomografice pentru a surprinde ansa intestinală herniată.(10)(11)(12)

Situaţiile cu simptomatologie acută reprezintă de asemenea o încercare dignostică, uşurată de necesitatea efectuării laparotomiei care tranşează etiologia sindromului ocluziv, rezolvând totodată această patologie.(13)

PREZENTARE DE CAZ

Va prezentăm cazul unei paciente de 36 ani, fără antecedente personale patologice, care se internează pentru vărsături bilioalimentare, dureri abdominale colicative şi scădere ponderală de 15 kg. într-o lună. Simptomatologia a debutat în urmă cu 2 luni cu dureri predominant epigastrice, vărsături şi scaune diareice, iar CT-ul abdominal efectuat atunci a stabilit diagnosticul de pancreatită acută edematoasă. Sub tratament specific evoluţia a fost iniţial favorabilă, urmată de o perioadă de acalmie, pentru ca apoi, în urmă cu 7 zile, starea pacientei să se agraveze brusc, reapărând vărsăturile intense, bilioalimentare, precum şi febră 38°, scaune de aspect melenic.

La momentul internării în serviciul de boli interne cu diagnosticul de pancreatită acută recidivată şi sinuzită maxilară bilaterală, pacienta era intens deshidratată, oligurică, palidă, TA 95/50 mmHg. Examenul biologic a evidenţiat patologic Hb 10.2g/dl, leucocite 24100/µl (cu frecvente hematii în ţintă, anulocite, eritroitroblaşti 2%, mielocite 2%, metamielocite 5%, nesegmentate 7%, trombocitoză – 652000/µl), Na 126,4 mmol/L, K 2,5 mmol/L, timp de protrombină Quick 32,7 sec(martor 11,6sec), activitate protrombinică 31%, INR 2,82, fibrinogen 841 mg/dl. Celelalte valori biologice ,inclusiv amilazele erau în limite normale.

Examenul fizic evidențiază tegumente şi mucoase palide şi uscate, puls de 120b/min, slab bătut, abdomen suplu, fără distensie, uşor sensibil la palpare profundă în epigastru, fără semne de iritație peritoneale. Zgomote intestinale de tonalitate joasă, de frecvență şi intensitate redusă. Examenul genital nu evidențiază nimic patologic. Tuşeul rectal evidențiază hemoroizi externi în coroană, iar în ampula rectală materii fecale de aspect melenic coafate de sânge proaspăt. Examenul ORL confirmă diagnosticul de sinuzită maxilară bilaterală.

Se efectuează o EDS ce evidențiază mucoasa antrală intens infiltrată, edemațiată, congestivă, şi un reflux duodeno-gastro-esofagian foarte intens, ridicându-se suspiciunea unui proces infiltrativ antral. Se efectuează examenul radiografic toracopulmonar ce identifică prezența unui revărsat pleural bilateral în cantitate mică, iar abdominal numeroase nivele hidroaerice proiectate în hipogastru şi flancul drept.

Examinarea tomografică a abdomenului evidențiază anse de intestin subțire dilatate, pline de lichid, unele cu pereți groşi, stază la nivelul colonului ascendent cu nivel hidroaeric, fără mase tumorale, adenopatii, ascită sau pneumoperitoneu.(fig.2) (fig.3)

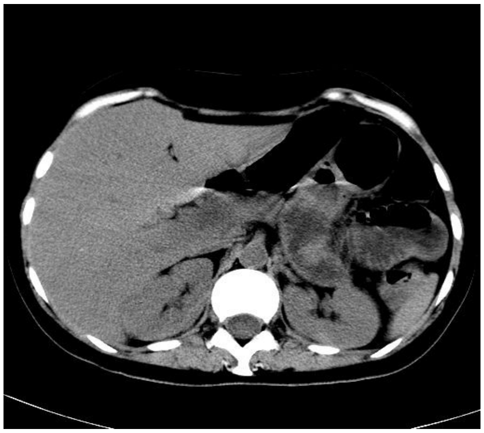

Fig.2 Evidențierea jejunului herniat retrogastric.

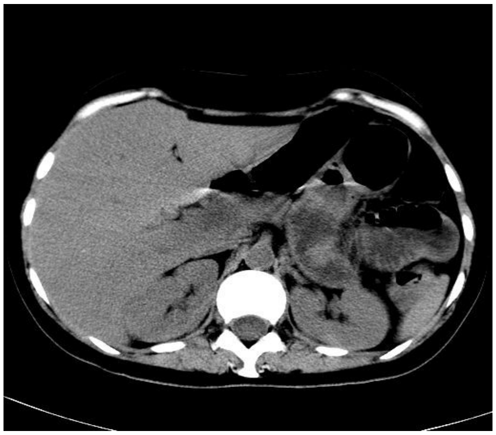

Fig.3 Aspect CT al anselor herniate retrogastric

Se instituie tratament intensiv de echilibrare hemodinamică şi electrolitică, se montează sondă urinară şi nazogastrică. După 24 ore starea pacientei se agravează, apar rectoragii cu sînge roşu, Hb ajunge la 5,6g/dl şi se solicită consultul chirurgical care, având în vedere toate datele, recomandă transferul în secția chirurgie şi intervenția chirurgicală în urgență.

Cu anestezie generală prin IOT, se efectuează o laparoscopie exploratorie care evidențiază anse enterale de aspect normal dar acoperite de false membrane, organe genitale interne şi apendice de aspect normal, etaj supramezocolic cu reacție inflamatorie acută intensă în regiunea pancreatică. Se decide conversia intervenției în laparotomie mediană xifo-ombilicală. Explorarea manuală a abdomenului evidențiază o breşă în mezocolonul transvers, în care se află încarcerată un segment jejunal de circa 40 cm., de la 10 cm. de unghiul dudenojejunal. După extragerea ansei herniate se evidențiază orificiul herniar situat la nivelul unei fosete paraduodenale Landzert, cu sac herniar ce ascensionează prepancreatic şi retrogastric până aproape de fornixul gastric, precum şi o altă fosetă, de mici dimensiuni, nelocuită, situată inferior de genunchiul duodenal.(fig.4)

Ansa enterală herniată este cu pereți groşi, edemațiați, congestivi , cu echimoze seromusculare, dar fără leziuni parcelare ischemice şi cu peristaltică prezentă.(fig.5)

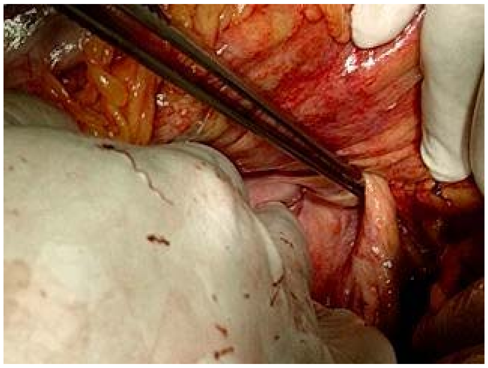

Fig.4 – Crificiul herniar paraduodenal stâng delimitat medial de duoden şi lateral de artera colică stângă.

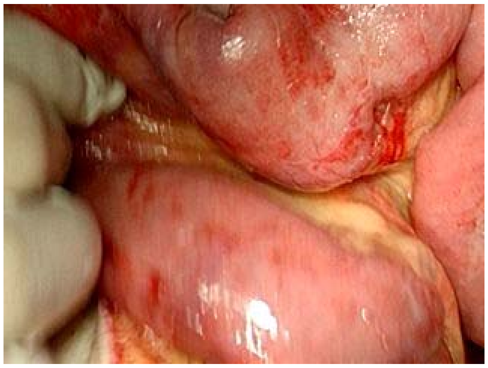

Fig.5 – Aspectul macroecopic al jejunului herniat.

Având în vedere starea biologică precară a pacientei, proximitatea unghiului duodenojejunal şi aspectul mai degrabă viabil al ansei herniate, se consideră că o rezecție ar avea un risc foarte mare de fistulizare, motiv pentru care intervenția se limitează la închiderea în burse etajate a celor două orificii herniare, lavajul cavității abdominale şi închiderea abdomenului.(fig.6) (fig.7)

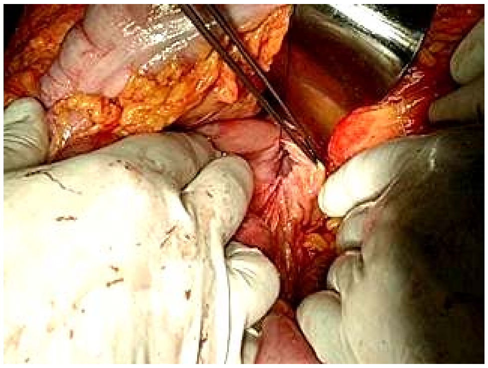

Fig.6 – Închiderea în bursă a celor două orificii herniare.

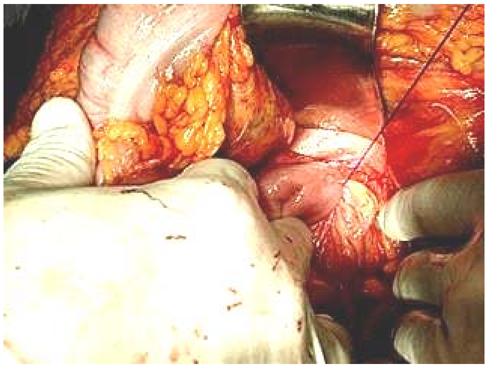

Fig.7 – Aspectul final al desființării orificiilor herniare.

Postoperator evoluția a fost lent favorabilă în primele 7 zile, cu îmbunătățirea semnificativă a stării generale, reluarea tranzitului pentru materii fecale normale, toleranță digestivă bună, corectarea valorilor biologice. Din ziua a 10a postoperator pacienta prezintă din nou câte 2-3 scaune melenice pe zi, survine o eviscerație blocată subcutanat de-a lungul întregii plăgi, probele hepatice se alterează treptat cu creşterea transaminazelor, a bilirubinei şi prăbuşirea coagulogramei. Hemogramele repetate indică o scădere a Hb până la 5,3g/dl, cu 20000leuc./µl şi trombocitopenie de 47000/µl. Se instituie tratament intensiv de reechilibrare, cu transfuzii repetate, plasmă proaspătă, antibioticoterapie cu spectru larg. Se efectuează o tomografie care evidențiază stomac cu conținut hidroaeric, anse intestinale cu pereți îngroşați, ficat cu consistență mult diminuată, aspect de eviscerație blocată, fără alte aspecte patologice intraabdominale.(fig.8).

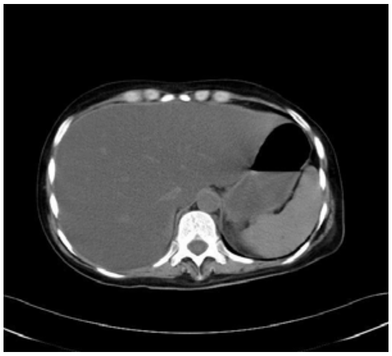

Fig.8 – Aspectul CT postoperaror cu hepatomegalie importantă.

Deoarece tratamentul intensiv aplicat pare ineficient, cu continuarea sîngerării digestive şi menținerea valorilor de Hb în jur de 5g/dl numai prin transfuzii zilnice de 1-2 unități de sânge, se considera această insuficiență hepatică cu punct de plecare un potențial focar septic intraperitoneal şi se hotărăşte o nouă intervenție chirurgicală, la 14 zile distanță de prima. Intraabdominal nu se găseşte nici un focar septic, ansa herniată inițial este de aspect aproape normal, cu pereți puțin îngroşați şi peristaltică bună, dar ficatul era mărit de volum şi cu consistență foarte scăzută, cu edem subcapsular. Se efectuează lavaj abundent şi cura eviscerației prin închiderea abdomenului intr-un strat cu fire de oțel.

Postoperator rezultatul hemoculturii sugerează o posibilă septicemie cu fungi pentru care se administrează tratament antifungic intravenos, concomitent cu terapia intensivă de susținere hepatică, alături de nutriția parenterală şi peros, considerându-se ca lanț etiopatogenic al insuficienței hepatice rezorbția masivă de compuşi toxici prin mucoasa segmentului intestinal afectat, prăbuşirea coagulării şi apariția sângerărilor difuze din întreg tractul digestiv.

Treptat prin continuarea tratamentului intensiv, starea pacientei se îmbunătățeşte, scaunele melenice dispar, coagulograma şi hemograma se normalizează, se reia toleranța digestivă, iar pacienta părăseşte spitalul la 30 zile de la internare, vindecată chirurgical.

DISCUȚII

Herniile paraduodenale sînt entități clinice rare, benigne, dificil de diagnosticat datorită unei simptomatologii nespecifice, prelungite, dar cu potențial evolutiv deosebit de grav.

Pe plan mondial s-au descris circa 400 de cazuri de hernii paraduodenale, majoritatea fiind identificate la bărbați, vîrsta medie fiind de 38,5 ani.

Clasificare

Ghahremani(14)a clasificat herniile interne în :

- hernii paraduodenale(50-55%)
- hernii prin hiatusul Winslow(6-10%)
- hernii transmezenterice(8-10%)
- hernii pericecale(10-15%)
- hernii intersigmoidiene(4-8%)
- hernii paravezicale(sub 4%)

La acestea se mai adaugă herniile perineale şi obturatorii.(fig.9)

plica duodenală inf.
recesul mezenterico-parietal
a. mezenterică sup. în mezenter
vase mezenterice inf.
aortă abdominală

Fig.9 – Localizarea herniilor interne.

Orientarea asupra diagnosticului poate fi sugerată de istoricul simptomatologiei dureroase intermitent a etajului abdominal superior, în lipsa constatării unei patologii biliare sau gastroduodenale şi confirmată de proba Pansdorf sau o tomografie abdominală cu dublu contrast, care ar putea surprinde ansa herniată prin foseta paraduodenală, elementul fundamental reprezentându-l suspiciunea medicului asupra existenței acestei patologii.

În cazurile cu evoluție cronică, se poate lua în considerare tratamentul laparoscopic, atât timp cât intestinele nu sînt foarte destinse sau nu prezintă elemente de încarcerare şi se poate extrage ansa din sacul de hernie. Închiderea în bursă a orificiului herniar necesită o atenție sporită doar față de artera colică stângă.

Situațiile acute sau cele cu diagnostic incert, impun laparotomia de urgență care stabileşte diagnosticul şi tratează afecțiunea. Totodată este necesar explorarea amănunțită a întregului abdomen pentru a exclude prezența şi a altor orificii herniare.

Cazul prezentat a surprins evoluția foarte severă a acestei patologii, prin asocierea unei insuficiențe hepatice determinată de creşterea segmentară a permeabilității mucoasei jejunale şi rezorbția masivă de compuşi toxici, ceea ce a fost aproape de a produce decesul pacientei.

Obezitatea factor de risc pentru litiaza biliară

Lt. dr. Dan Aurel BĂNUȚ[*], lt.-col. dr. Maria AVRAM*,
cpt. dr. Vasile MILOIU*

OBIECTIV: Prezentarea unui studiu care aduce date privind prevalența litiazei biliare şi rolul obezității ca factor de risc în apariția acestei boli, prin efectuarea unui triaj clinic şi ecografic asupra unui grup populațional semnificativ numeric (2348 de subiecți).
MATERIAL ŞI METODĂ: Lotul inclus in studiu a fost supus unui screening ecografic pentru depistarea pacienților litiazici. De asemenea, subiecților luați în studiu li s-au efectuat măsurători antropometrice, s-a determinat înălțimea, greutatea, indicele de masă corporală. Indicele de masă corporală a fost calculat după formula IMC= greutate (kg)/ înălțime(m)^2. S-a determinat frecvența obezității la subiecții cu litiază biliară comparativ cu cei fără litiază biliară considerându-se obeze persoanele cu IMC peste 30. Studiul a inclus persoane cu vârste cuprinse între 18 şi 90 de ani, pacienți internați, precum şi persoane care efectuau controale medicale periodice.
REZULTATE ŞI CONCLUZII: Datele obținute evidențiază prevalența crescută a obezității la subiecții litiazici comparativ cu cei nelitiazici (40,15%-19,65%). Detaliind pe sexe am obținut următoarele rezultate: la sexul feminin obezitatea este prezentă la 32,16% dintre pacientele cu litiază față de 19,48% la nelitiazice, în timp ce la sexul masculin 53,93% dintre litiazici sunt obezi față de 19,84% dintre nelitiazici. Rezultatele obținute arată că în zona studiată obezitatea este un factor litogen major la ambele sexe, cu un plus pentru sexul masculin la care peste 50% dintre litiazici au fost obezi. Obezitatea fiind un factor de risc influențabil, pentru prevenirea apariției calculilor biliari se impun o serie de măsuri de profilaxie primară dintre care un rol însemnat îl au igiena de viață şi cea alimentară cu combaterea obezității şi hiperlipidemiei.

litiază biliară **obezitate** **factor de risc**

ABSTRACT
Objective: to present the relation between obesity and biliary lithiasis by clinical and echographic triage on 2348 patients.
Material and method: was achieved an echographic screening to discover the patients having lithiasis. Was determined the frequency of obesity in patients having biliary lithiasis versus group with no lithiasis. The age of the patients hospitalized and of the personnel which effected periodical medical control ranged from 18 to 90 years.
Results and conclusions: the results suggest the prevalence of obesity in subjects with lithiasis was higher than in patients without lithiasis (40,15%-19,65%). In women the obesity is present in 32,16% of the patients with lithiasis and in 19,48% of the subjects without lithiasis. In men the obesity is present in 53,93% of the patients with lithiasis and in 19,84% of the subjects without lithiasis. The obesity is an important lithogen factor both the men and the women, but in men over 50% of the patients having lithiasis were obese. The obesity is an important risk factor for development of biliary lithiasis. The primary prophylaxis – lifestyle and alimentary hygiene in correlation with the control of the obesity and the hyperlipidemy - prevents the development of biliary lithiasis
Key words: biliary lithiasis, obesity, risk factor

IPOTEZĂ DE LUCRU

Litiaza biliară a devenit o importantă problemă socioeconomică datorită prevalenței sale în continuă creştere. Interrelația dintre obezitate şi litiază a fost amplu dezbătută în literatura de specialitate. S-au efectuat numeroase studii epidemiologice, care au confirmat frecvența mai mare a calculilor biliari la obezi (1,2,3,4). Mecanismele sunt complexe. Masa adipocitară crescută duce la o creştere a sintezei de colesterol (5) şi la o suprasaturare a bilei în colesterol (6,7). Concentrația molară a colesterolului biliar *a jeun* la femeile obeze fără calculi este de 10,8% față de 6,8% la femeile normoponderale (8). Activitatea HMGCoA-reductazei creşte în obezitate în contextul unui aport alimentar şi a unei insulinemii crescute (9,10). Cu toate progresele efectuate, mecanismul complet al discoliei litogene în obezitate nu este elucidat.

---

[*] Secția de Medicină Internă, Spitalul de Urgență Militar, Cluj-Napoca.

MATERIAL

În studiu a fost inclus un lot populațional de 2348 de subiecți cu vârste cuprinse între 18 şi 90 de ani, care s-au adresat laboratorului de ultrasonografie pentru examen ecografic abdominal. Studiul s-a derulat în perioada 2006-2007.

Din lotul global de 2348 de subiecți, 1236 au fost de sex feminin, iar 1112 de sex masculin. Lotul a cuprins persoane din toate mediile sociale, atât din mediul urban, cât şi rural. Au fost incluşi în studiu studenți, salariați din toate domeniile de activitate şi pensionari. Grupul studiat a inclus şi un număr de 75 de subiecți colecistectomizați pentru litiază biliară

METODĂ

Subiecților luați în studiu li s-au efectuat măsurători antropometrice, s-a determinat înălțimea, greutatea, indicele de masă corporală. Indicele de masă corporală a fost calculat după formula IMC = greutate (kg)/ înălțime (m)^2. S-a determinat frecvența obezității la subiecții cu litiază biliară comparativ cu cei fără litiază biliară considerându-se obeze persoanele cu IMC peste 30.

REZULTATE

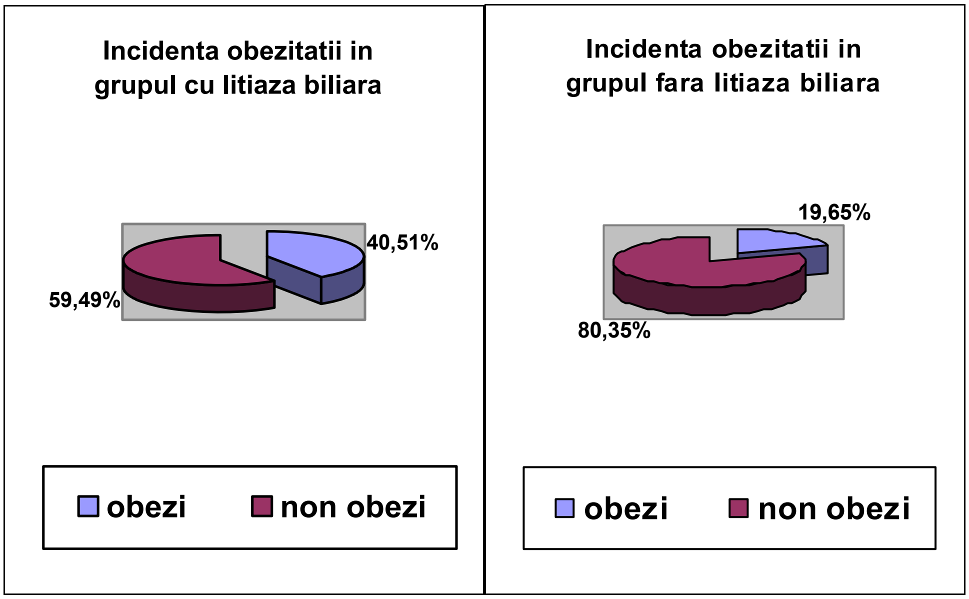
Frecvența obezității la subiecții litiazici comparativ cu cei nelitiazici.

1. Date generale

Incidența obezității este prezentată mai jos comparativ la lititazici, respectiv nelitiazici.

TABEL 1. Incidența litiazei biliare în loturile studiate

Lot	Număr	Obezi	Non obezi
L.B.	232	94 (40,51%)	138 (59,49%)
Fără L.B.	2116	416 (19,65%)	1700 (80,35%)



Incidenta obezitatii in grupul cu litiaza biliara

Incidenta obezitatii in grupul fara litiaza biliara

Figura 1

Datele obținute indică un procent aproximativ dublu de obezi în grupul litiazic comparativ cu cel nonlitiazic.

2. Date comparative pe sexe

Datele obținute la sexul feminin sunt redate în tabelul 2 şi figura 2.

TABEL 2. Prevalența obezității la femeile litiazice, respectiv nelitiazice

Lot	Număr	Obeze	Nonobeze
L.B.	143	46 (32,16%)	97 (67,84%)
Fără L.B.	1093	213 (19,48%)	880 (80,52%)

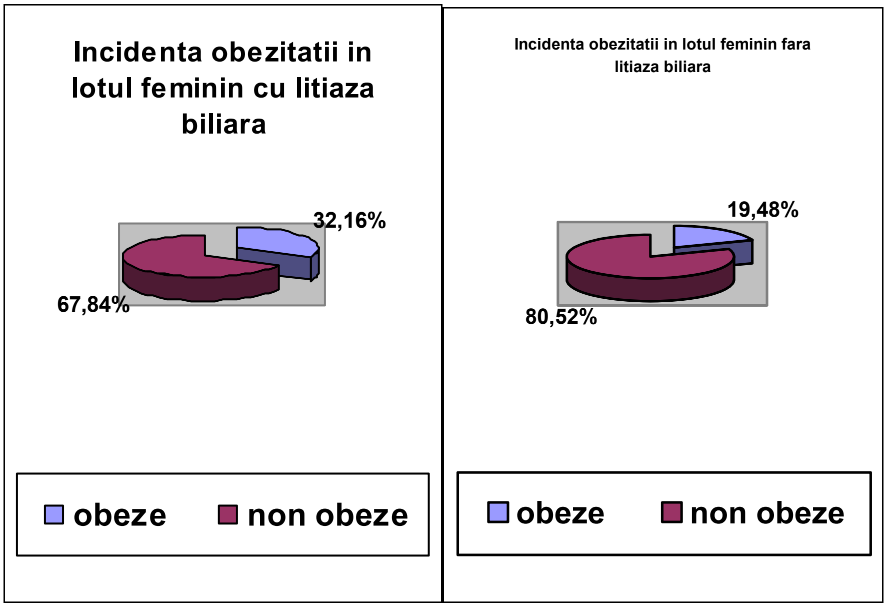


Figura 2

Putem observa la sexul feminin o diferență înalt semnificativă statistic în ceea ce priveşte prezența obezității între grupul litiazic şi cel nelitiazic.

Datele obținute la sexul masculin sunt redate în tabelul 3 şi figura 3.

TABEL 3. Prevalența obezității la bărbații litiazici, respectiv nelitiazici

Lot	Număr	Obezi	Non obezi
L.B.	89	48 (53,93%)	41 (46,07%)
Fără L.B.	1023	203 (19,84%)	820 (80,16%)

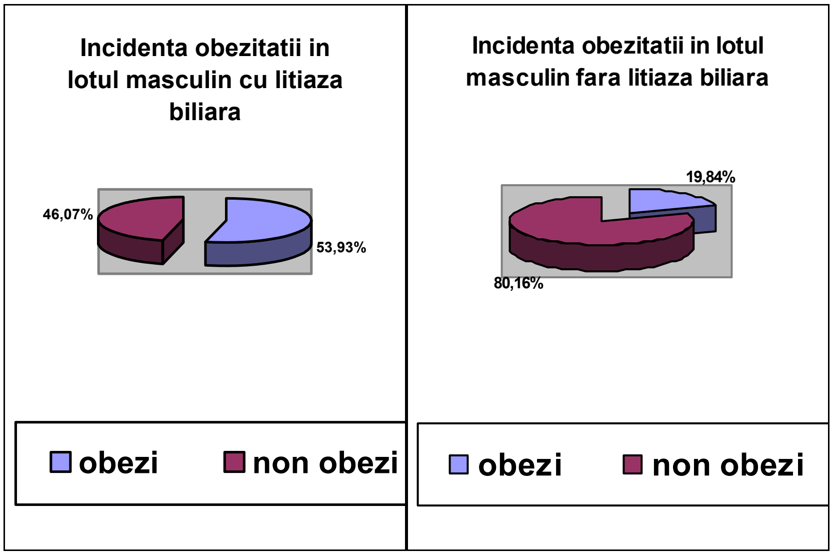

Figura 3

Se poate obseva la sexul masculin că mai mult de jumătate din litiazici prezentau obezitate (53,93%). Comparativ, la subiecții nelitiazici obezitatea era prezentă doar la 19,84%.

3. Date obținute pe grupele de vârstă

Datele obținute pe fiecare decadă de vârstă la lotul global sunt reprezentate în tabelul 4. Se poate observa pe fiecare grup de vârstă o frecvență mai mare a litiazei biliare la subiecții obezi comparativ cu cei neobezi.

TABEL 4. Frecvența obezității pe decade de vârstă la întreg lotul

Vârsta	Număr	L.B		Fără L.B	
		obezi	non obezi	obezi	non obezi
Sub 20 ani	67	1	0	5 (7,57%)	61
21-30 ani	215	2 (22,22%)	7	21(10,19%)	185
31-40 ani	392	6 (28,57%)	15	45(12,12%)	326
41-50 ani	416	21(41,17%)	30	71(19,45%)	294
51-60 ani	522	31(42,46%)	42	111(24,72%)	338
61-70 ani	495	22(43,13%)	29	116(26,12%)	328
71-80 ani	197	9 (45%)	11	39(22,03%)	138
81-90 ani	44	2 (33,33%)	4	8 (21,05%)	30

TABEL 5. Frecvența obezității pe decade de vârstă la femei

Vârsta	Număr	L.B.		Fără L.B.	
		obeze	non obeze	obeze	non obeze
Sub 20 ani	23	1	0	3(14,28%)	18
21-30 ani	68	1(16,66%)	5	12(19,35%)	50
31-40 ani	185	2(13,33%)	13	19 (11,17%)	151
41-50 ani	293	10(29,41%)	24	43(16,60%)	216
51-60 ani	310	16(37,20%)	27	63(23,59%)	204
61-70 ani	252	11(36,66%)	19	53(23,87%)	169
71-80 ani	82	4 (36,36%)	7	17(23,94%)	54
81-90 ani	23	1 (33,33%)	2	3 (15%)	17

La femeile litiazice observăm o frecvenţă crescută a obezităţii comparativ cu cele nelitiazice în decadele 5-9 de viaţă.

TABEL 6. Frecvenţa obezităţii pe decade de vârstă la bărbaţi

Vârsta	Număr	L.B.		Fără L.B.	
		obezi	non obezi	obezi	non obezi
Sub 20 ani	44	0	0	3(6,81%)	41
21-30 ani	147	2(66,66%)	1	26(18,05%)	118
31-40 ani	207	3(50%)	3	38 (18,90%)	163
41-50 ani	123	9(52,94%)	8	32(30,18%)	74
51-60 ani	212	16(53,33%)	14	47(25,82%)	135
61-70 ani	243	12(57,14%)	9	36(16,21%)	186
71-80 ani	115	5 (55,55%)	4	17(15,88%)	90
81-90 ani	21	1(33,33%)	2	4 (22,22%)	14

La bărbaţii litiazici, începând cu a treia decadă de viaţă frecvenţa obezităţii este semnificativ crescută comparativ cu lotul nelitiazic

DISCUŢII ŞI CONCLUZII

Numeroase studii situează obezitatea la loc de frunte ca factor de risc pentru apariţia litiazei biliare (11,12,13,14,15,16,17,18,19). Riscul litogen legat de obezitate variază în funcţie de vârstă, sex şi importanţa excesului ponderal. Un studiu efectuat la Cluj-Napoca pe 30 de pacienţi litiazici confirmă existenţa unei corelaţii pozitive între concentraţia colesterolului biliar şi greutatea corporală relativă (4).

Obezitatea duce la o secreţie şi excreţie crescută de colesterol, ce are drept consecinţă suprasaturarea bilei în colesterol (6,7). Aceasta, la rândul ei, crează condiţii favorabile pentru dezvoltarea calculilor de colesterol. Conform studiilor efectuate de Angel şi Herbst greutatea litiazicilor depăşeşte în medie cu 20% cifra ideală şi invers peste 30% dintre marii obezi au calculi. Într-un studiu efectuat la Clinica Medicală III a Spitalului de Gastroenterologie din Cluj-Napoca, 53,3% dintre pacienţii litiazici au fost obezi (11). Un alt studiu efectuat pe un lot feminin având în medie un surplus ponderal de 60 de kg a depistat prezenţa litiazei la 40% (20). Semnificativ s-a dovedit la femei excesul ponderal reprezentat la nivelul abdomenului (15).

Rezultatele obţinute în studiul nostru confirmă datele din literatură, care consideră obezitatea un important factor litogen. Am remarcat la lotul sudiat o incidenţă semnificativ mai mare a obezităţii la litiazici comparativ cu pacienţii nelitiazici (40,15%-19,65%). Detaliind pe sexe se observă aceeaşi corelaţie pozitivă între obezitate şi litiaza biliară. Astfel, la sexul feminin obezitatea este prezentă la 32,16% dintre pacientele litiazice faţă de 19,48% la nelitiazice, în timp ce la sexul masculin 53,93% dintre litiazici sunt obezi faţă de 19,84% dintre nelitiazici. Urmărind frecvenţa obezităţii la litiazici pe grupe de vârstă, observăm că aceasta creşte progresiv din decada a doua până în decada a opta. Acest fapt relevă ponderea dominantă a factorilor exogeni în litogeneză la vârstnici. Practic, cele două patologii se suprapun tot mai frecvent odată cu înaintarea în vârstă.

La lotul de femei litiazice frecvenţa maximă a obezităţii se remarcă în decadele 5-8 de viaţă. La sexul masculin frecvenţa obezităţii la litiazici este ridicată începând cu a doua decadă de viaţă şi se menţine până într-a opta.

Pe toate grupele de vârstă şi la ambele sexe, obezitatea este mai frecventă în grupul litiazic comparativ cu cel nelitiazic.

Rezultatele obținute ne duc la concluzia că în zona studiată obezitatea este un factor litogen major la ambele sexe, cu un plus pentru sexul masculin la care peste 50% dintre litiazici au fost obezi. Nu trebuie uitat faptul că obezitatea este un factor de risc influențabil, astfel pentru prevenirea apariției calculilor biliari se impun o serie de măsuri de profilaxie primară dintre care un rol însemnat îl au igiena de viață şi cea alimentară cu combaterea obezității şi hiperlipidemiei.

Evaluare comparativă a tehnicilor de diagnostic în litiaza căii biliare principale

**Dr. Gabriel IANOŞI*, lt.-col. medic conf. univ. dr. Dorin MERCUŢ*,
dr. Daniela NEAGOE**, col.(r) dr. Mihai POPESCU*,
dr. Cristian SILOŞI*, dr. Emil TRAŞCĂ*, dr. Aurelia RESCEANU***,
lt.-col. (r) dr. Alexandru ANDRIŢOIU****, col. (r) dr. Paul DEMETRIAN*****,
dr. Oana COANDĂ**, student Răzvan MERCUŢ********

Litiaza căii biliare principale (CBP) este o patologie cu care orice chirurg digestiv se confruntă. În literatura de specialitate s-au propus, de-a lungul timpului, mai multe soluţii terapeutice, dar şi instrumente matematice de tip scoruri, care ar permite selectarea pacienţilor cu risc de litiază hepatocoledociană, limitând necesitatea unor tehnici invazive. Studiul nostru are rolul de a determina, în mod retrospectiv, sensibilitatea şi specificitatea diferitelor tehnici diagnostice în scopul de a alege o baterie de teste care să prevadă, la un grad cât mai înalt, preoperator, riscul de litiază CBP.

Studiul a vizat un număr de 1074 pacienţi supuşi colecistectomiei la care s-a evaluat eficienţa prognostică a simptomatologiei, precum şi a unor explorări biologice şi imagistice pentru diagnosticarea litiazei CBP. Prelucrarea statistică a constatat că durerea în hipocondrul drept asociată icterului ($p<0,05$) ori descoperirea icterului la pacienţii internaţi în urgenţă ($p<0,01$) sunt singurele asocieri clinice cu valoare diagnostică. Bilirubina serică cu valori duble faţă de normal are valoare predictivă importantă ($p<0,005$) la pacienţii cu litiază a căii biliare principale, iar evidenţierea preoperatorie a litiazei coledociene (ultrasonografic ori computer tomografic) este un puternic factor predictiv pentru diagnosticul de litiază CBP ($p<0,001$). Constatarea dilatării hepato-coledocului, ecografic ori CT, nu a oferit rezultate semnificative în studiul nostru.

Concuzionând, afirmăm că litiaza căii biliare principale, fie că se dezvoltă *de novo* sau evoluează ca o complicaţie a litiazei veziculare, este o afecţiune a cărei simptomatologie a ieşit din standardele clasice, diagnosticul său necesitând obligatoriu o explorare imagistică preoperatorie sau intraoperatorie performantă.

---

litiaza căii biliere principale (CBP) diagnostic

ABSTRACT

Common bile duct lithiasis is a frequent disease in a general surgical department. There were many diagnostic and therapeutic solutions proposed over the time in the literature. The aim of our study is to determine, by retrospective mode, sensibility and specificity of a few diagnostic features in order to predict the risk of common bile duct lithiasis.

We included in our study 1074 patients in which we achieved cholecystectomy and we evaluated the predicting efficiency of a symptomatology and a few biological and imagistical examens. Our results showed that abdominal right-upper quadran pain associated with jaundice ($p<0,05$) or jaundice at a patient in emmergency condition ($p<0,01$) has diagnosis role. Serum bilirubine with levels duble over the normal ($p<0,005$) and detecting (ultrasonographically or by CT scan) a lithiais inside of a CBD ($p<0,001$) represent other predictors of the disease.

Common bile duct lithiasis, even if is developing *de novo* or as a complication of vesicular lithiasis is a disease with a different symptoms compared with classical needing, for a correct diagnosys, a performant imagistic examination.

Key words: common bile duct stones, diagnosis

INTRODUCERE

Litiaza căii biliare principale este o patologie cu care orice chirurg digestiv se confruntă. Chiar dacă metodele diagnostice, după cum şi soluţiile terapeutice, au evoluat spectaculos în acest domeniu, se constată, totuşi, o serie de dificultăţi în managementul hepatocoledocului litiazic.

Circa 10-20% dintre pacienţii prezentând litiază veziculară simptomatică au şi litiază de cale biliară principală (1). Simptomatologia acesteia din urmă este, adesea, greu de diferenţiat de cea a litiazei veziculare. Pe de altă parte implicaţiile clinice ale litiazei reziduale, deşi disputabile, pot fi serioase, detectarea litiazei căii biliare principale înainte de practicarea colecistectomiei laparoscopice fiind extrem de importantă (2,3).

Există mai multe strategii care propun managementul pacienţilor cu risc ridicat de litiază coledociană şi care urmează să fie supuşi colecistectomiei laparoscopice, prin abord primar endoscopic (colangiopancreatografie endoscopică retrogradă asociată ori nu sfincterotomiei endoscopice), pur laparoscopic, ori prin asocierea celor două căi fie în aceeaşi şedinţă operatorie, fie separat. Propunerea şi folosirea unor instrumente matematice de tip scoruri permite selectarea pacienţilor cu risc de litiază a căii biliare principale, limitând, totodată, efectuarea unor tehnici invazive (cum este ERCP) (4).

Studiul nostru are rolul de a determina, în mod retrospectiv, sensibilitatea şi specificitatea diferitelor tehnici diagnostice în scopul de a alege o baterie de teste care să prevadă, la un grad cât mai înalt, preoperator, riscul de litiază CBP.

MATERIAL ŞI METODĂ

Studiul s-a desfăşurat în cadrul Clinicii de Chirurgie a Spitalului Clinic de Urgenţă Militar „Dr. Ştefan Odobleja” din Craiova şi a parcurs două stadii. Primul stadiu a fost reprezentat de o cercetare retrospectivă, care a inclus pacienţi supuşi colecistectomiei laparoscopice în intervalul ianuarie 2002-decembrie 2006. În cadrul acestei etape s-a determinat sensibilitatea şi specificitatea mai multor date clinico-paraclinice în depistarea litiazei coledociene:

- vârsta;
- semne clinice şi simptome: durere tipică în hipocondrul drept, febră, frison, icter sclero-tegumentar, alterarea stării generale, greţuri, vărsături;
- date biologice: bilirubina serică, GOT, GPT, gamma-glutamiltranspeptidaza, fosfataza alcalină, albuminemia;
- date ecografice: diametrul căii biliare principale ori vizualizarea ecografică a calculilor;
- date computer-tomografice: evidenţierea calculilor, diametrul căii biliare principale, altă patologie asociată;
- colangiografia intraoperatorie.

Al doilea stadiu al studiului nostru s-a desfăşurat de-a lungul întregului an 2007 când, într-un mod prospectiv, au fost evaluate rezultatele obţinute în prima fază a cercetării, respectiv bateria de date cu eficienţă diagnostică predictivă pentru litiaza hepatocoledociană.

Au fost incluşi, în prima fază a studiului nostru, 1074 pacienţi, dintre care 812 au fost femei şi 262 bărbaţi, cu o vârstă medie de 57,1 ani (limite între 15 şi 92 de ani). Am exclus din studiu pacienţii care au prezentat sfincterotomie endoscopică anterioară, hepatită acută sau cronică, pancreatită cronică, boli inflamatorii intestinale ori antecedente de alcoolism. De asemenea, au fost excluşi din studiu pacienţi, care au prezentat neoplazii ce reduc speranţa de viaţă la mai puţin de 2 ani şi, de asemenea, sarcina în evoluţie.

Parametrii amintiţi mai sus au fost înregistraţi prin cercetarea foilor de observaţie la toţi pacienţii incluşi în studiu, fiind excluşi, de asemenea, acei pacienţi la care aceştia nu s-au putut obţine ori au fost neconcludenţi. Determinarea diametrului hepatocoledocului a fost efectuată de doi specialişti în ecografie, cu experienţă, considerându-se pozitivă o valoare mai mare sau egală cu 8 mm.

Raportarea rezultatelor s-a făcut faţă de constatările intraoperatorii şi relativ la colangiografia intraoperatorie ori la ERCP postoperatorie efectuate (Fig. 1 şi 2). Datele obţinute sunt prezentate în continuare.

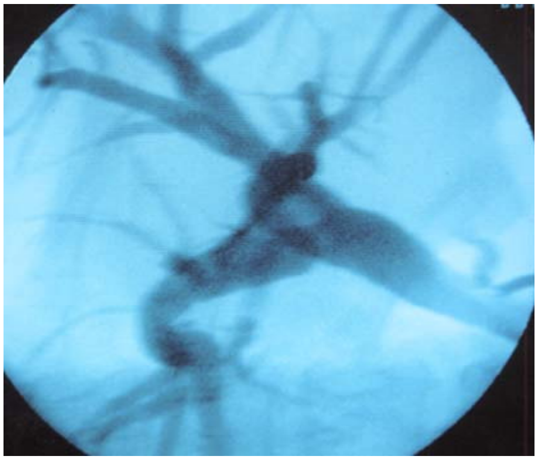

Fig. 1. Litiază coledociană – aspect colangiografie intraoperatorie (Colecția dr.Ianoşi)

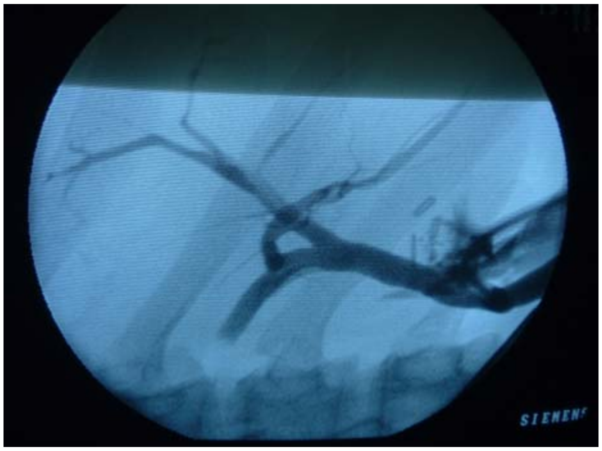

Fig. 2. Litiază coledociană – aspect colangiografie intraoperatorie (Colecția dr.Ianoşi)

Analiza statistică a loturilor de pacienți s-a făcut prin teste ale statisticii descriptive: diferențele dintre loturi au fost calculate folosind testul t, după folosirea inițială a testelor de normalitate Kolmogorov-Smirnov şi Shapiro-Wilk W, egalitatea variantelor fiind verificată prin testul F. În cazul testului t am folosit şi alternativa sa neparametrică, testul Mann-Whitney U, iar pentru a evalua diferențele dintre loturi multiple de pacienți am folosit testul ANOVA. Pentru stabilirea corelațiilor dintre variabile a fost utilizat calculul coeficientului de corelație.

REZULTATE

Din cei 1074 de pacienți supuşi colecistectomiei în perioada luată în studiu, aşa cum aminteam mai sus, au fost excluşi pacienții care au prezentat o sfincterotomie endoscopică anterioară, hepatită acută sau cronică, pancreatită cronică, boli inflamatorii intestinale ori antecedente de alcoolism, toate aceste situații putând altera concluziile, în special în ceea ce priveşte datele clinice culese. A rezultat un număr de 789 de pacienți, dintre care 612 femei şi 177 bărbați la care s-a efectuat evaluarea retrospectivă. Dintre aceştia 84 au prezentat litiază de cale biliară principală (50 de femei şi 34 de bărbați, cu un raport F:B = 1,5:1). Repartizarea acestora pe grupe de vârstă a arătat o incidență mai mare a litiazei hepatocoledociene la vârstele mai înaintate (peste 50 ani) după cum se constată în Fig.3a şi 3b.

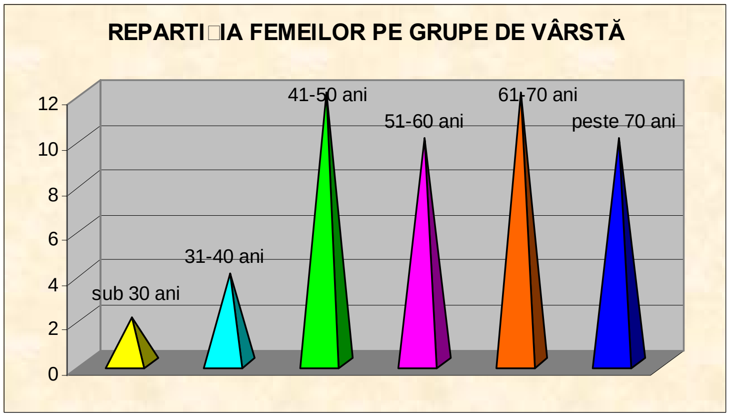

Fig. 3a. Repartiția femeilor cu litiază coledociană pe grupe de vârstă

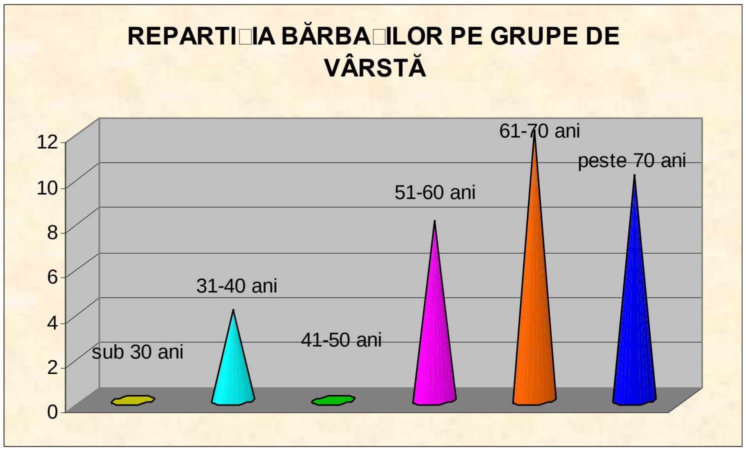

Fig. 3b. Repartiția bărbaților cu litiază coledociană pe grupe de vârstă

În ceea ce priveşte simptomatologia, chiar dacă, în termeni generali, datele vechi din literatură se păstrează, am constatat foarte rar triada clasică Charcot (durere – febră – icter) şi chiar mai rar pentada Reynolds. Durerea a constituit motiv de internare pentru doar 60% dintre pacienți, existând, însă diferențe în cazul asocierii colecistitei acute când durerea a fost prezentă la 81% dintre pacienți.

Febra a fost consemnată la 26 de pacienți (31%), iar frisonul la chiar mai puțini (19 pacienți – 24%). Icterul ar trebui să fie semnul clinic patognomonic pentru obstrucția căii biliare principale. Corelația cu nivelul bilirubinei serice este absolut, evidențiat şi în studiul de față, însă am constatat că o mare parte dintre pacienții incluşi în loturile noastre nu au prezentat acest simptom. Astfel, dintre cei 84 de pacienți cu litiază hepato-coledociană, numai 52 (62%) au prezentat icter, la 32 (32%) neconstatând acest simptom nici măcar în antecedente ori în cursul puseelor evolutive ale bolii. Situația s-a modificat radical, însă, în momentul în care am comparat cazurile internate prin urgență cu cele internate într-un mod programat. Dacă în cazul urgențelor simptomul principal care a condus pacientul la spital a fost icterul, la pacienții internați în mod programat, acest simptom a fost prezent doar în ceva mai mult de 50% dintre cazuri (16 pacienți din 30).

Dintre celelalte simptome constatate la internare, doar dispepsia de tip hepato-biliar, respectiv grețurile şi vărsăturile au fost consemnate într-un procent mai important (50, respectiv 26 dintre cei 84 de pacienți cu litiază a căii biliare principale). Restul simptomelor au fost prezente în procente mici, nesemnificative, adesea fiind incluse în cortegiul simptomatologic al afecțiunilor concomitente ori ale complicațiilor bolii litiazice hepatocoledociene.

Prelucrarea statistică a datelor clinice a constatat că doar durerea în hipocondrul drept ($p<0,05$) şi icterul la pacienții internați în condiții de urgență ($p<0,01$) sunt semnificative statistic pentru diagnosticul litiazei căii biliare principale, toate celelalte simptome oferind rezultate nesemnificative statistic.

Datele biologice efectuate la toți aceşti pacienți incluşi în studiu au fost: bilirubina serică, transaminazele serice (ALAT, ASAT şi gamma-glutamiltranspeptidaza), fosfataza alcalină şi albuminemia serică. Considerând drept valori de referință bilirubinemia peste valoarea normală am obținut un număr foarte mare de rezultate fals-pozitive ($p>0,5$), motiv pentru care am luat în calcul doar valorile acesteia peste dublul normalului. În aceste condiții bilirubina serică a devenit un indice cu valoare predictivă relativ mare pentru litiaza coledociană ($p<0,005$).

Fosfataza alcalină, enzimă de colestază, a avut valoare predictivă moderată ($p<0,1$) în studiul nostru, în timp ce valorile gamma-glutamiltranspeptidazei şi ale albuminei serice nu au avut semnificație statistică.

Determinarea diametrului căii biliare principale s-a efectuat ecografic în toate cazurile, iar în situații selective şi computer-tomografic; aceste metode imagistice au permis şi evidențierea calculilor la nivelul hepatocoledocului. Am înregistrat un singur rezultat fals-pozitiv în cazul constatării preoperatorii a unei litiaze coledociene, motiv pentru care considerăm (şi datele statistice o confirmă) că evidențierea litiazei coledociene este un factor predictiv puternic pentru diagnostic ($p<0,001$). Diametrul căii biliare principale determinat preoperator ecografic nu a fost dovedit ca factor predictiv. Aceeaşi determinare efectuată computer tomografic pare să aibă o eficiență diagnostică superioară, însă numărul de cazuri limitat nu ne permite să tragem o concluzie clară.

DISCUȚII

Formele asimptomatice de litiază a căii biliare principale sunt, probabil, frecvente, însă prevalența acestora este imposibil de precizat. Pentru ca un astfel de diagnostic să fie cât mai real este necesară efectuarea colangiografiei intraoperatorii în cursul oricărei colecistectomii. În realitate, colangiografia intraoperatorie se practică în manieră rutinieră în doar 10-15% dintre centrele cu experiență din lume, majoritatea clinicilor chirurgicale preferând efectuarea acestei manevre într-un mod selectiv, la pacienții care prezintă date preoperatorii sugestive pentru litiaza hepatocoledociană (5). În Clinica de Chirurgie a Spitalului Militar din Craiova practicăm colangiografia intraoperatorie, fie în cursul colecistectomiilor clasice, fie laparoscopice, în manieră selectivă.

În fața unui bolnav prezentând dureri în hipocondrul drept, însoțite sau nu de un sindrom dispeptic de tip hepatobiliar, cu modificări ale probelor hepatice este indicată, ca primă manevră diagnostică, practicarea unei ecografii abdominale (6). Este o tehnică sigură, ce nu presupune iradierea pacientului şi poate fi practicată indiferent de valorile pe care le constatăm în cadrul setului de analize biologice recoltate acestuia. Chiar dacă are o sensibilitate şi specificitate limitate comparativ cu alte explorări imagistice, tehnica are valoare prin disponibilitatea sa generală şi prin posibilitatea efectuării sale la orice pacient. Diagnosticul pozitiv ultrasonografic complet al patologiei căii biliare principale trebuie să răspundă la trei întrebări (7): dacă există un obstacol în calea fluxului biliar, să consemneze localizarea acestui obstacol şi care este natura sa (Fig.4).

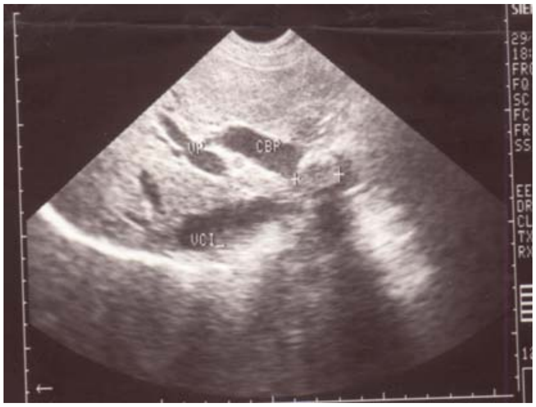

Fig. 4. Litiază coledociană – aspect ecografic (Colecția dr.G.Ianoşi)

Mai mult, investigația poate fi folosită ca screening înaintea efectuării altor explorări imagistice: dacă se constată dilatarea căilor biliare intrahepatice se continuă explorarea cu o colangiografie transparietohepatică, o cauză medicală de icter fiind în principal suspectată; dacă, din contră, se constată dilatarea căilor biliare extrahepatice, atunci se va prefera efectuarea colangiografiei retrograde endoscopice, la aceasta putând fi asociată şi o metodă endoscopică de drenaj biliar, sfincterotomia endoscopică cu extragerea calculilor (8). Ultrasonografia armonică este o tehnică ultrasonografică îmbunătățită, care permite ameliorarea calității imaginii, în special la pacienții la care explorarea este dificilă (9). Tot pe acelaşi principiu funcționează şi ecoendoscopia, care este o metodă neinvazivă introdusă relativ recent în arsenalul metodelor de investigare a căii biliare principale, reprezentând şi o importantă modalitate de evaluare a colestazei extrahepatice deoarece, prin plasarea transductorului în duoden, evită interferențele determinate de aerul intestinal ceea ce îi conferă o vizualizare foarte bună a căilor biliare extrahepatice. Rezoluția ecoendoscopiei biliare este sub 1 mm (chiar 0,1 mm) ceea ce o face utilă, la acest nivel, pentru detectarea microlitiazei biliare ori pentru evaluarea stricturilor benigne sau maligne ale ductului biliar.

Imagistica radiologică prin tomografie computerizată îmbunătăţeşte rezultatele obținute prin explorarea ultrasonografică, în special la nivel retroduodenopancreatic unde ecografia dă cele mai multe rezultate fals-negative. Explorarea căii biliare principale prin rezonanță magnetică nucleară se constituie într-o manevră diagnostică şi mai performantă ale cărei sensibilități şi specificități sunt cuprinse între 91-100%, respectiv 72-100% (10).

Colangiopancreatografia retrogradă endoscopică (CPRE) ar putea fi considerată drept cea mai veche investigație modernă a litiazei căii biliare principale (6). Este o explorare invazivă şi este cotată cu un risc de cca 1-2% de dezvoltare a unei pancreatite acute în special la tineri (11). Chiar dacă tinde să fie înlocuită în algoritmul diagnostic de către ecoendoscopie pe măsură ce aceasta devine accesibilă tot mai multor centre medicale, CPRE rămâne o explorare cu dublu rol, diagnostic şi terapeutic, fiind prima etapă, absolut necesară, în abordul terapeutic al litiazei CBP prin sfincterotomie endoscopică.

Studiul nostru s-a efectuat pe un număr relativ limitat de pacienți, fiind vorba despre experiența din ultimii 5 ani a unei singure clinici chirurgicale, însă trebuie remarcat faptul că datele obținute se apropie de ceea ce consemnează literatura de specialitate.

CONCLUZII

1. Litiaza căii biliare principale, fie că se dezvoltă *de novo*, fie că evoluează ca o complicație a litiazei veziculare, este o afecțiune a cărei simptomatologie a ieşit din standardele clasice, diagnosticul său necesitând obligatoriu o explorare imagistică preoperatorie sau intraoperatorie.
2. Durerea în hipocondrul drept, asociată icterului, ori descoperirea icterului la pacienții internați în urgență sunt singurele asocieri clinice cu valoare diagnostică.
3. Bilirubina serică cu valori duble față de normal are valoare predictivă importantă la pacienții cu litiază a căii biliare principale.
4. Evidențierea preoperatorie a litiazei coledociene (ultrasonografic ori computer tomografic) este un puternic factor predictiv pentru diagnosticul de litiază CBP; evidențierea dilatării hepatocoledocului, ecografic ori CT, nu a oferit rezultate semnificative în studiul nostru.

GLIOBLASTOMUL MULTIFORM
- elemente de actualitate

Acad. Prof. Dr. Leon DĂNĂILĂ[*], Dr. Cristian NĂSTASE[**]
Dr. Lidia GHEORGHIŢESCU* Dr. Marian MITRICĂ**

Glioblastomul multiform (GBL) poate fi considerat prin malignitatea sa înaltă „capul de serie" al astrocitoamelor difuze de tip fibrilar şi reprezintă o provocare neuro-oncologică. Autorii prezintă o trecere în revistă a principalelor caracteristici generale ale acestei entităţi nosologice şi evidentiază tratamentul complex multimodal aplicat pentru stoparea evoluţiei acestei tumori, prelungirea supravieţuirii şi asigurarea unei calităţi a vieţii acceptabile. Evoluţia GBL este gravă cu durată medie de supravieţuire sub 1 an.

glioblastom tratament multimodal calitatea vieţii

Abstract
The glioblastoma may be considered by its high malignity the "first of all" fibrillar-type diffuse astrocytoma and represents a neuro-oncological challenge. The authors present a main features review of this nosological entity and highlight the multimodal complex therapy to perform in order to stop the tumor evolution, life extension and the quality-of-life assurance. The GBL evolution is a severe one having an average of survival up to a year no more.

Key words: Glioblastoma, multimodal therapy, quality of life

Consideraţii generale

Definiţie. Glioblastomul este o tumoră cu origine neuroectodermală şi reprezintă cea mai malignă tumoră astrocitară cerebrală, fiind compusă, în cea mai mare parte, din astrocite neoplazice slab diferenţiate. Trăsăturile histopatologice includ polimorfism celular, atipii nucleare, activitate mitotică înaltă, proliferare microvasculară cu tromboze vasculare şi necroze. În general, glioblastomul afectează adulţii, cu predilecţie între 45 şi 70 ani şi de obicei, se localizează în emisferele cerebrale (10). Glioblastoamele se pot dezvoltă din astrocitoame difuze de gradul II, astrocitoame anaplazice (glioblastom secundar), dar în mod frecvent ele se manifestă după o evoluţie clinică scurtă, „de novo", fără prezenţa unei leziuni anterioare maligne (glioblastom primar).

Diferenţierea între GBL primar şi secundar a fost facută pentru prima oară de Scherer în 1940 care spunea: "din punct de vedere biologic şi clinic, GBL secundare se dezvolta din astrocitoamele difuze prin dediferenţiere şi trebuie deosebite de GBL primare (de novo)".

Acestea din urmă reprezintă majoritatea, apar în jurul vârstei de 55 de ani, sunt mai frecvente la bărbaţi şi au o istorie clinică scurtă, de obicei mai puţin de 3 luni, manifestându-se "de novo", fără evidenţă clinică sau histopatologică a unui astrocitom de grad mic preexistent(10).

Gradare. Glioblastomul multiform şi variantele sale (GBL cu celule gigante şi gliosarcomul) corespund gradului IV de malignitate (OMS).

Incidenta. Glioblastomul este cea mai frecventă tumoră cerebrală, reprezentând aproximativ 12-15% din toate neoplasmele intracraniene şi 50-60% din tumorile astrocitare (4). Vârsta medie de apariţie este 56 de ani, iar bărbaţii sunt mai frecvent afectaţi (sex ratio 1,5/1). În Europa, SUA şi Canada, incidenţa este de 2-3 cazuri noi la o sută de mii de oameni pe an (8).

---

[*] Institutul Naţional de Neurologie şi Boli Neurovasculare Bucureşti - Clinica de Neurochirurgie
[**] Spitalul de Urgenţă Militar Central „Dr. Carol Davila" Bucureşti – Secţia de Neurochirurgie

Localizare. Glioblastoamele se dezvoltă, de cele mai multe ori, din substanța albă subcorticală a emisferelor cerebrale (3).
În statistica noastră, localizările cele mai frecvente au fost: lob temporal 29%, lob parietal 25%, lob frontal 24% şi lobul occipital 16%. Localizările combinate fronto-temporale sau temporo-parietale sunt destul de frecvente(10). Tumora infiltrează structurile cerebrale adiacente: cortexul adiacent, ganglionii bazali, emisferul contralateral, pedunculii cerebrali, etc. Glioblastoamele intraventriculare sunt foarte rare, precum şi cele cerebeloase şi intraspinale (13).

Vârsta şi distribuția pe sexe. Glioblastomul poate apărea la orice vârstă, dar afectează în special adulții cu vârsta cuprinsă între 45 şi 70 ani, media fiind 56 ani (8). Bărbații par a fi mai frecvent afectați decât femeile (1,5/1).

Trăsături clinice. Istoricul clinic al bolii este de obicei scurt (mai puțin de 8 luni în mai mult de 50% din cazuri), dacă neoplasmul nu s-a dezvoltat din astrocitoame difuze de gradul II sau astrocitoame anaplazice (glioblastom secundar). Deseori, după o manifestare epileptică cu simptome neurologice nespecifice, pacienții prezintă dureri de cap şi tulburări de personalitate, iar semnele specifice ale hipertensiunii intracraniene devin rapid evidente (1).
Simptomatologia clinică a glioblastoamelor multiforme este similară cu a astrocitoamelor difuze anaplazice cu diferența ca primele se însoțesc de deficit neurologic focal cu debut brusc şi rapid evolutiv. Astrocitoamele difuze de grad II şi astrocitomul anaplazic infiltrează țesutul cerebral intact fără a-l distruge, comparativ cu GBL care pe lângă efectul de masă produce şi distrucția tisulară cerebrală, efectul clinic fiind deficitul neurologic focal. Hemoragia cerebrală acută poate sublinia debutul clinic al unui GBL dar aceasta se întâmplă în cazuri rare (3).

Neuroimagistica. Pe examinarea CT craniocerebrala, glioblastomul prezintă o formă neregulată, cu o zonă periferică circulară (ring like) care captează intens substanța de contrast şi o zonă centrală (hipodensă), ce reprezintă necroza – fig.1 (13).

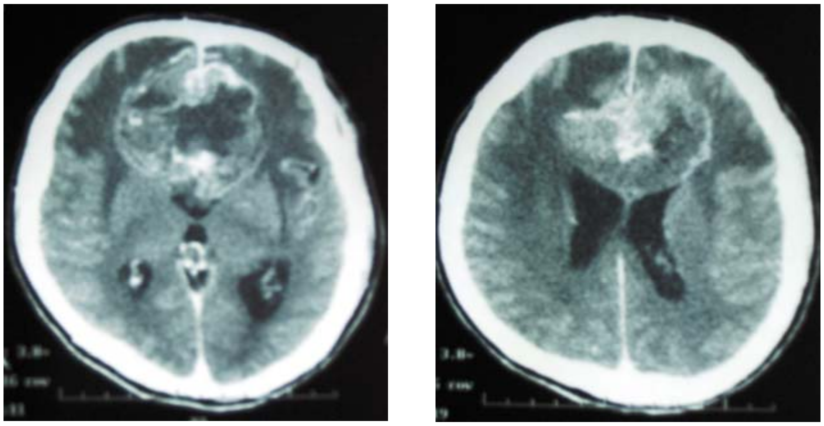

Fig. 1. Aspect CT-scan de glioblastom multiform bifrontal
(se observă tumora hipercaptantă a substanței de contrast marginal, cu necroză centrală şi intens edem peritumoral)

Imaginile obținute prin RM reflectă o marcată heterogenitate intratumorală, dată de hemoragie (de vârste diferite), necroze şi hipercelularitate în grade variabile. În secvența T1, imaginile RMN evidențiază o structură inelara periferică hipercaptantă de contrast, ce corespunde ariei tumorale cu celularitate crescută şi hipervascularizație (fig.2). Aceasta structură nu reprezintă marginea externă a tumorii, celule tumorale infiltrative putând fi uşor identificate chiar şi la 3 cm de marginea tumorală. În secvența T2 se observă focare de necroză chistică hiperintensă şi arii hipercelulare care au intensitate mai redusă, înconjurate de un edem vasogenic cu semnal crescut (5).

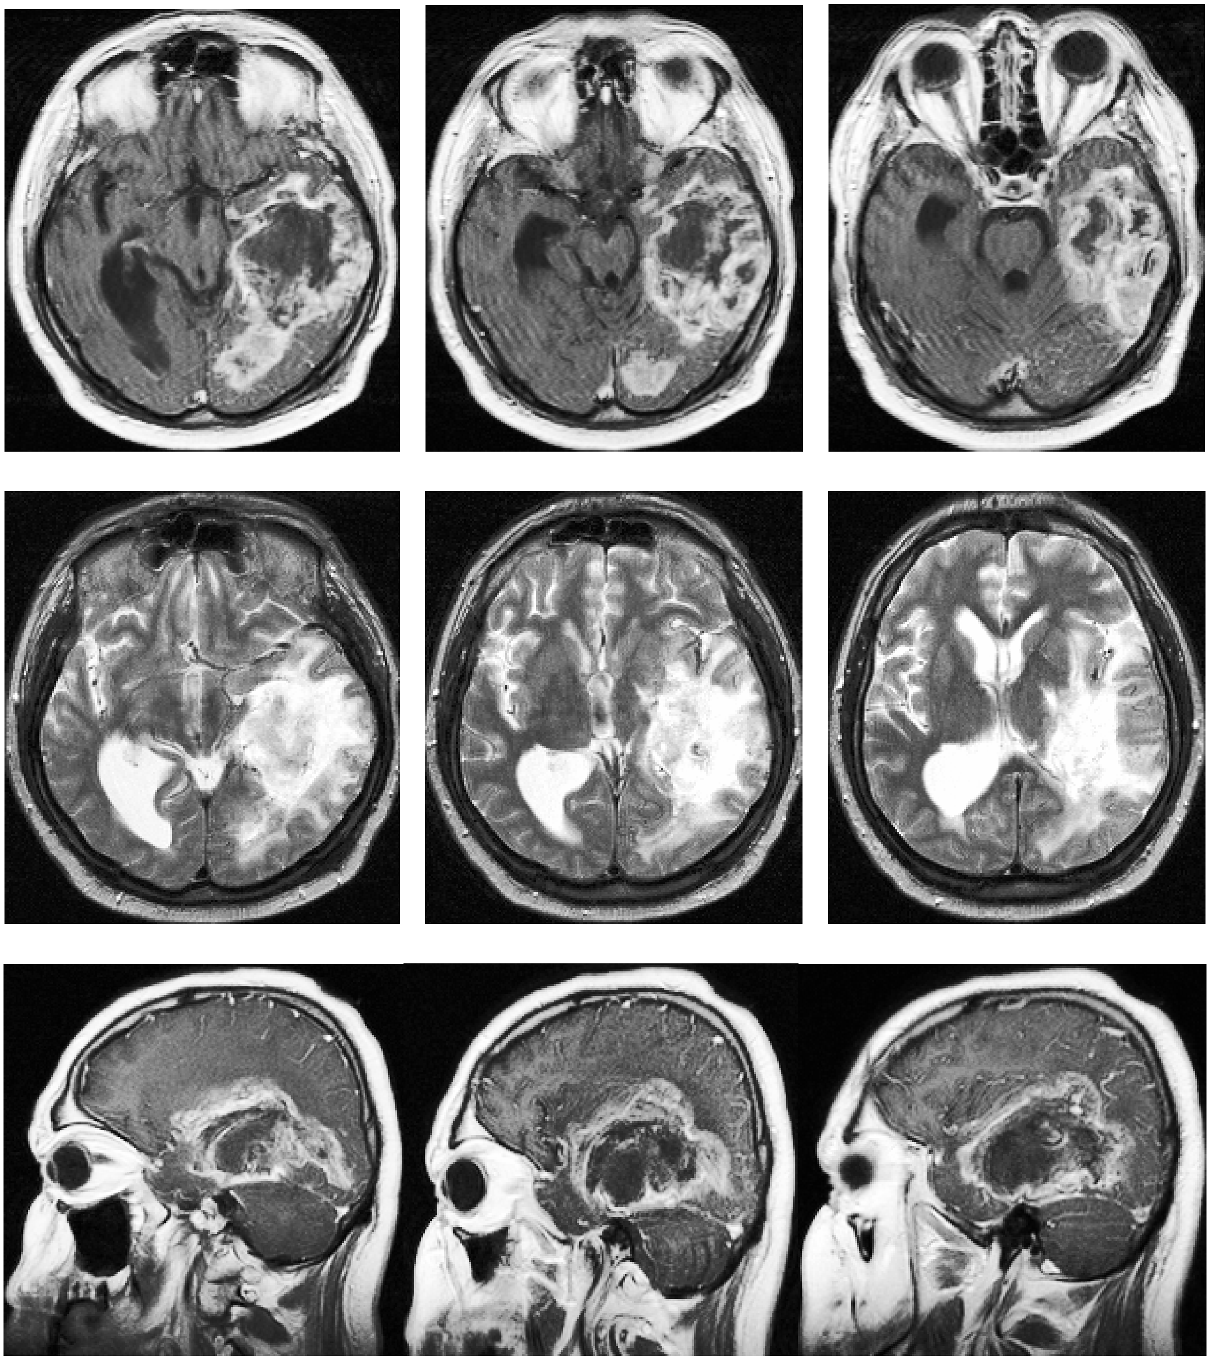

Fig.2. Aspect IRM de glioblastom multiform temporal stâng
(secvențe T1 axial şi sagital cu substanță de contrast şi T2 axial);

Imaginile obținute prin PET scan evidențiază consumul regional de glucoză, strâns corelat cu gradul de hipercelularitate. Trebuie făcută diferența dintre recidiva tumorii şi radionecroză, pe baza PET, care arată creşterea metabolismului glucozei în țesuturile recidivate față de hipometabolismul din radionecroză (7).

Uneori, GBL-ul este o leziune multicentrică, putând exista două tumori sincrone (simultan), detectate în focare independente în momentul primei evaluări sau metacrone, adică pot apărea la momente diferite în timp şi pretând la confuzii cu metastazele. O parte din aceste focare tumorale au aspecte histologice diferite, ceea ce ar pleda pentru originea lor policlonală (11) (fig. 3).

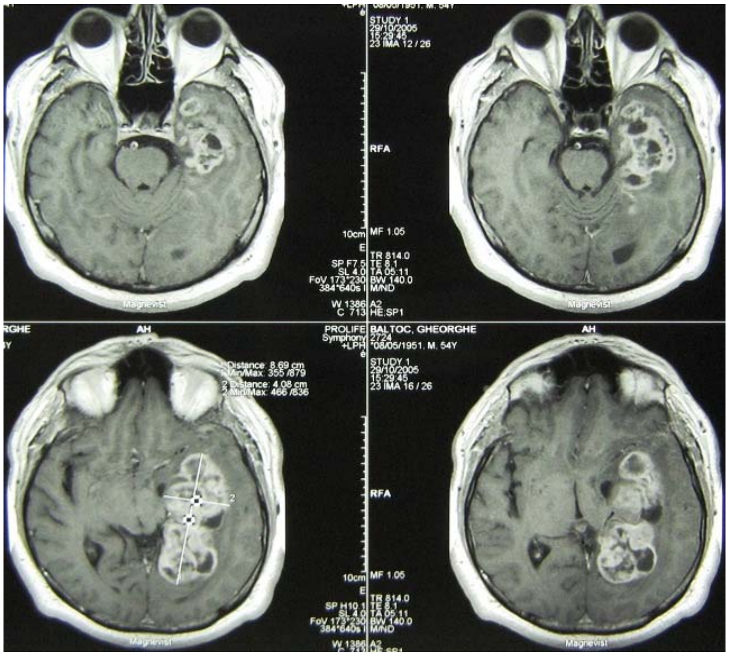

Fig. 3. Aspect IRM (secventă T1 – axial) de glioblastom multicentric temporal şi parietal, se observă extensia tumorală prin tracturile de substanță albă;

Neuropatologie. Macroscopic, GBL este o tumoră imprecis delimitată, suprafața de secțiune arătând zone de culoare gălbuie (necroză), ce poate ocupa 80-90% din masa tumorii, înconjurată de zone periferice gri-murdar, unde masa tumorală are o consistență moale şi zone brun-roşiatice care reprezintă hemoragii de vârste diferite (10). Uneori, hemoragiile mari pot produce confuzii cu accidentele vasculare hemoragice (fig. 4).

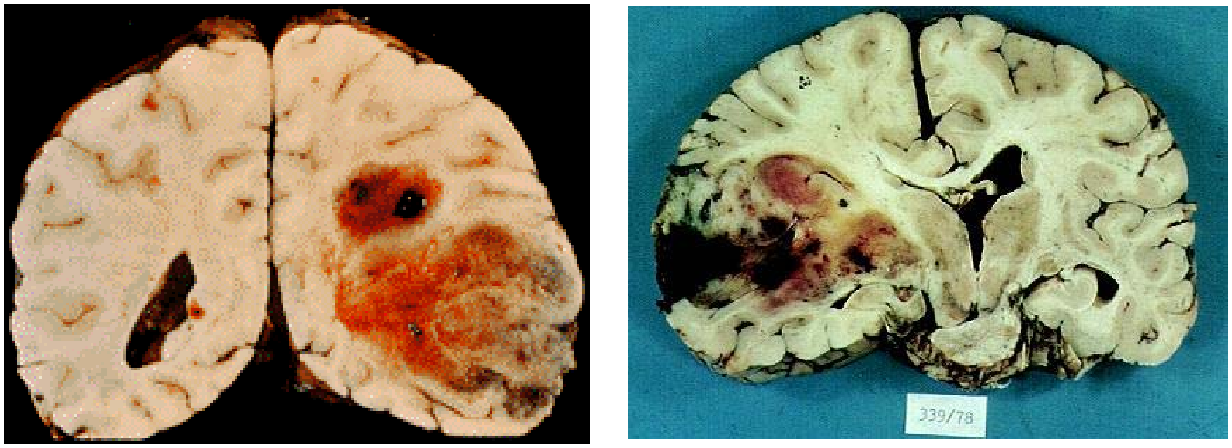

Fig. 4. Aspecte macroscopice de glioblastom multiform – secțiuni coronale;

Zona centrală pseudochistică vizibilă macroscopic conține un țesut tumoral necrotic lichefiat de culoare brun-roşiatică datorată hemoragiei recente şi produşilor de degradare ai hemoglobinei şi are pereți de obicei neregulați, spre deosebire de astrocitoamele de grad inferior care posedă un chist bine delimitat (14). Această zonă de necroză centrală este înconjurată de o zonă hipercelulară asemănătoare unui inel. Cele mai multe glioblastoame apar în emisferele cerebrale, intraparenchimatos, cu epicentru în substanța alba, dar pot ajunge în contact cu leptomeningele şi dura mater (4).

Aspectele microscopice sunt variabile; se prezintă ca o tumoră evident astroglială, datorită tramei fibrilare eozinofile, populată de o mare diversitate de celule astrocitare anaplazice având mari

diferențe de volum, de tinctorialitate, un aspect pleomorf, cu numeroase atipii celulare şi nucleare, precum şi celule multinucleate, gigante, aneuploide cu aspect monstruos (acestea din urmă fiind considerate ,,marca" de GBL). Dacă aceste celule gigante multinucleate domină aspectul histopatologic, denumirea ,,glioblastom cu celule gigante" este justificată (9).
Datorita anaplaziei crescute, uneori este greu de identificat originea astrocitară a tumorii (fig.5,6,7 şi 8).

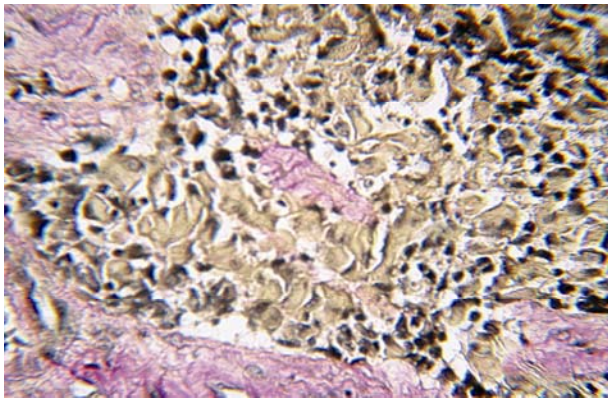

Fig. 5. Insulă celulară epitelioidă în GBL mitoze atipice) în GBL

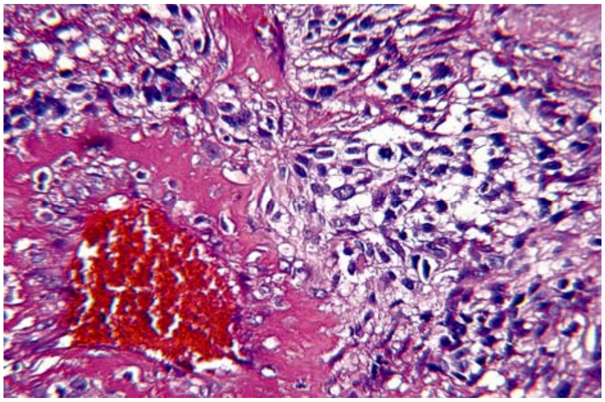

Fig. 6. Aspecte de anaplazie celulară (atipii, mitoze atipice) în GBL

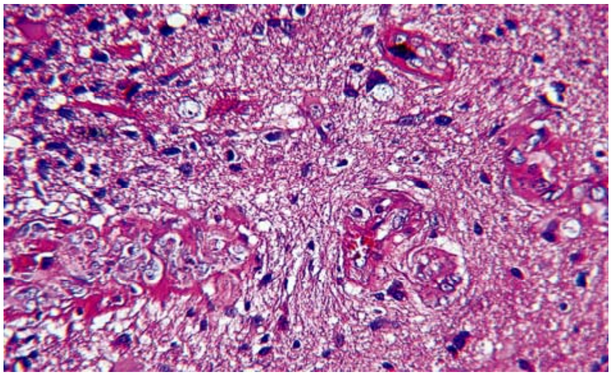

Fig. 7. Proliferari microvasculare

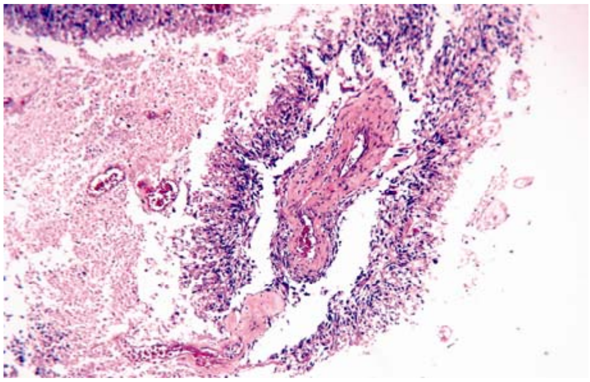

Fig.8. Zonă întinsă de necroză; rămân viabile celule tumorale dispuse perivascular

Pe lângă prezența celulelor gliale anaplazice, diagnosticul de GBL se precizează şi pe baza activității mitotice, a proliferării vasculare şi a necrozei. Proliferarea vasculară este mai exprimată în jurul focarelor necrotice şi la periferia zonei infiltrative (10) (fig. 5, 6, 7). Uneori pot fi recunoscute printre celulele anaplazice şi astrocite de tip fibrilar şi gemistocite, recunoscând tranziția de la grade inferioare la gradul IV. GBL-ul secudar prezintă centrul tumoral cu aspect de glioblastom, ce se pierde treptat într-un astrocitom de grad III şi ulterior într-o periferie de tip astrocitom fibrilar de grad II (13).

În ciuda evoluției clinice de scurtă durată, aceste tumori sunt de cele mai multe ori surprinzător de mari şi pot afecta mai mult decât un lob cerebral; unele pot infiltra pedunculul cerebral spre trunchiul cerebral sau corpul calos spre emisferul contralateral ("butterfly glioblastoma" fig .9).

Diseminare şi metastazare. Deşi tendința de a infiltra țesutul cerebral adiacent este o trăsătură comună tuturor tumorilor astrocitare difuze, GBL-ul are tendința naturală spre invazie, infiltrare şi distrucție a țesutului cerebral adiacent. O trăsătură caracteristică a GBL este extensia prin corpul calos spre emisferul cerebral contralateral, creând o leziune simetrică ("butterfly glioma").

Posibilitatea de extensie a fost observată şi prin capsula internă, fornix, pedunculi cerebrali, comisura albă anterioară sau radiaţiile optice etc.

Aceste structuri pot apărea lărgite, dilatate sau distorsionate şi pot servi drept cale de diseminare, permiţând extensia tumorii la distanţă şi sugerând de multe ori aspectul de GBL multifocal (11). "Guerilla cells", celule maligne călătoare, pot fi identificate şi la distanţă de 3-4 cm de tumora propriu-zisă, de obicei în zona edematoasă peritumorală. Aceste celule tumorale nediferenţiate pot migra şi la distanţe mult mai mari, uneori chiar la 6-7 cm de-a lungul tracturilor de substanţă albă sus menţionate (2) (fig.10).

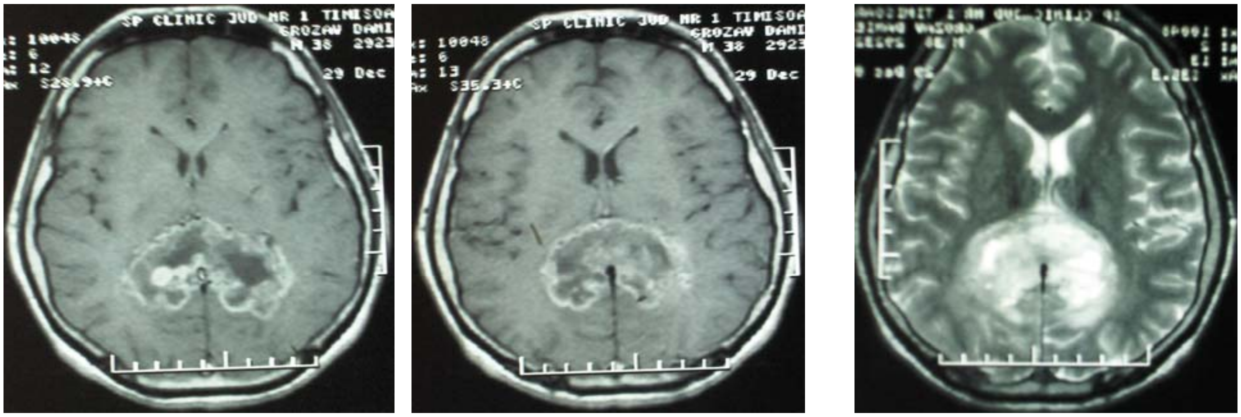

Fig.9. Aspect IRM de glioblastom multiform – „în fluture”(butterfly glioma), se observă extensia contalaterală prin spleniusul corpului calos;

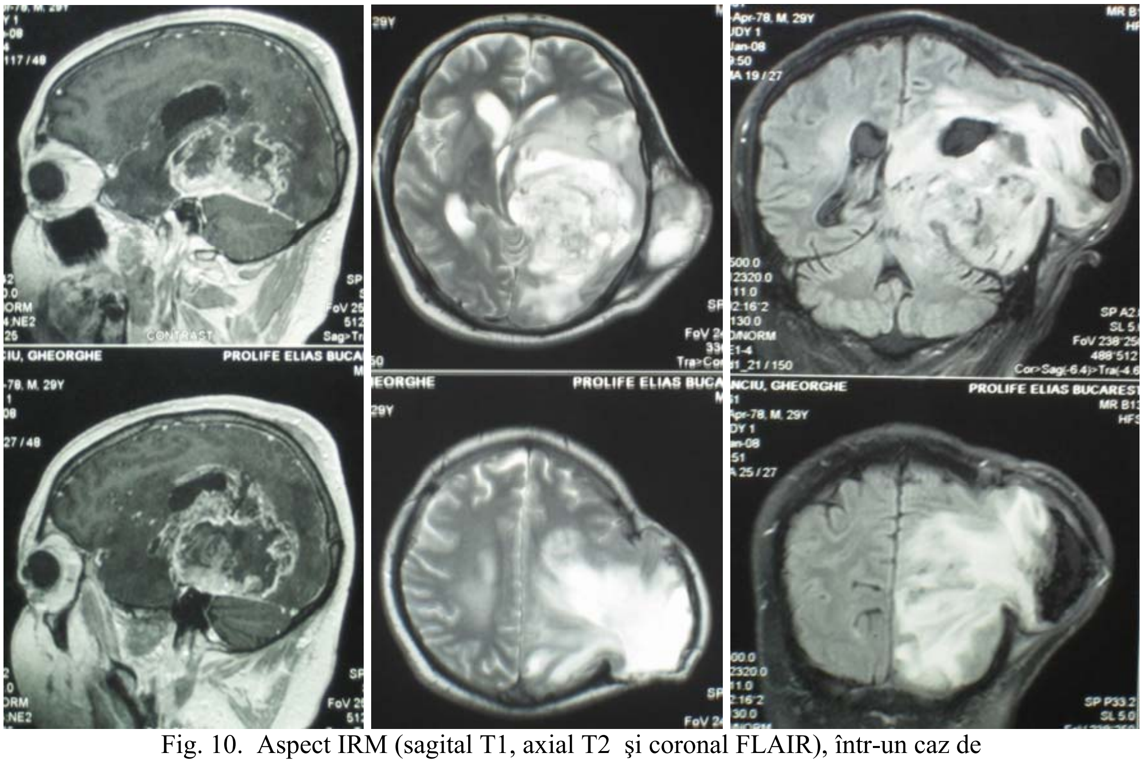

Fig. 10. Aspect IRM (sagital T1, axial T2 şi coronal FLAIR), într-un caz de glioblastom temporo-parietal stâng, operat iterativ şi recidivat;

Extensia de-a lungul spațiilor perivasculare este altă cale tipică de diseminare a GBL, dar invazia intraluminală vasculară este extrem de rară – celulele tumorale nu pot strabate elastina din structura peretelui vascular, nesecretând elastaza. Diseminarea pe cale hematogenă se produce doar în timpul manevrelor chirurgicale, spre țesuturi extraneurale (13). Metastazarea intraperitoneală via drenaj ventriculo-peritoneal a fost observată şi se poate produce (2).

În ciuda agresivității şi gradului crescut de infiltrare tumorală, tendința GBL de a invada spațiul subarahnoidian este destul de rară, metastazele via LCR la distanța fiind ocazionale (14). Penetrarea durei mater, sinusurilor venoase sau a osului se produce în mod excepțional (10).

Imunohistochimia. Imunoreactivitatea la GFAP este neomogenă şi inconstantă. Ea dovedeşte doar originea glială a celulelor tumorale, dar nu şi pe cea astrocitară. Celulele tumorale fixează mai omogen şi mai intens S100. Uneori GBL prezintă şi markeri epiteliali cum ar fi citokeratina. Vimentina este nespecifică fiind de folos doar ca indicator al imunoviabilității țesutului. Indicii de marcare ai proliferării celulare cu Ki67/MIB-1 evidențiază o fracție de creştere tumorală situată între 15-20% (3).

Genetica moleculară. Transformarea malignă a celulelor neuroepiteliale se produce diferit în cazul glioblastoamelor secundare comparativ cu glioblastoamele primare (11). În glioblastoamele secundare procesul dediferențierii celulare se realizează secvențial, prin achiziția seriată a modificărilor genice. Procesul începe prin afectarea genei ce codifică proteina supresoare tumorală p53 ("polițistul genomului"), însoțită sau nu de pierderea heterozigozității cromozomului 17p (care conține gena menționată). Aceasta este cea mai precoce modificare genică, detectabilă la majoritatea astrocitoamelor difuz infiltrative de grad II şi se asociază frecvent cu supraexprimarea PDGF (platelet-derived growth factor) si a receptorului său PDGFR (15). Transformarea în astrocitom anaplazic este consecința deletiilor alelice ale cromozomilor: 9p, 13q şi mai rar, a amplificării 12q. Toate aceste modificări fac parte dintr-un singur ciclu reglator complex, cu rol critic, al diviziunii celulare - ciclul reglator p16/p15/CDK4/CDK6/Rb. Afectarea ciclului menționat conduce la fosforilarea proteinei Rb, permițând celulei să avanseze din faza G1 spre faza S (inițiind astfel diviziunea mitotica).

În cele din urmă se produce amplificarea EGFR (epidermal growth factor receptor). Acesta este oncogena cel mai frecvent amplificată în astrocitoamele anaplazice şi în peste 50% din glioblastoamele de toate tipurile (11).

Glioblastoamele primare prezintă modificări genice de mare amploare care se produc brutal, fără secvențialitate. Ele asociază supraexprimarea EGFR cu deleția cromozomului 10. În afara acestor mutații genice principale se mai descriu şi afectări ale unor gene supresoare tumorale, cum sunt: DCC (deleted in colorectal cancer), deleția alelică a cromozomului 19q şi pierderea heterozigozității cromozomului 22q (11).

Tratament si prognostic.

Tratamentul este cel chirurgical, urmat de radioterapie convențională externă sau brahiterapie, chimioterapie. Tratamentul chirurgical trebuie să pună în balanță pe de o parte supraviețuirea mai lungă după rezecții tumorale mai largi, cu afectarea pe de altă parte a calității vieții. Excizia chirurgicală cât mai completă aduce o multitudine de avantaje printre care:

- scade efectul de masă;
- reduce frecvența hemoragiilor în patul tumoral (prin ablația vaselor de neoformatie);
- facilitează terapiile adjuvante (atât radioterapia cu variantele sale cât şi chimioterapia);
- îmbunătățeşte statusul neurologic al pacienților;
- îmbunătățeşte controlul medicamentos al crizelor epileptice etc.

Pacienții cu GBL multiform, tratați numai chirurgical, au un timp mediu de supraviețuire de cca.16 săptămâni (13).

Biopsia stereotactică poate fi luată în considerare în situațiile când:

- tumora este situată într-o zonă elocventă a creierului,
- tumora este de mici dimensiuni, cu localizare profundă,

- când pacientul prezintă deficit neurologic minim,
- pentru a face diferența între un GBL și o altă tumoră care poate fi tratată cu succes prin iradiere (ex. limfom), ambele fiind compatibile imagistic, pretând la confuzie (12)

Corticoterapia are eficiență în tratarea glioamelor cerebrale prin reducerea metabolismului cerebral al glucozei și reducerea edemului vasogenic (3).

Radioterapia produce modificări specifice, care trebuie recunoscute, atât pentru a putea urmări eficiența acesteia, cât și în scopul evitării unor confuzii diagnostice. Astfel, după un interval mai scurt pentru brahiterapie, mai lung pentru radioterapia convențională externă, tumora prezintă focare întinse, confluente de necroză, direct proporționale cu doza administrată (7). Necroza exprimă o perioada de repaus tumoral, caracterizată prin paucicelularitate, pleomorfism celular și mai ales prin apariția unei populații astrocitare gigantocelulare care reprezintă o formă de degenerescență tumorală. După câteva luni se produce selecția unei subpopulații celulare cu agresivitate ridicată, aproape lipsită de radiosensibilitate (2). Doza uzuală de raze X folosită este de 50-60 Gy. Radioterapia externă (whole brain) nu a dovedit o eficiență mai mare comparativ cu iradierea focală (7). Radioterapia convențională adițională chirurgiei poate extinde perioada de supraviețuire cu aproximativ 39 de săptămâni. Radiochirurgia prin "gamma-knife" are efect bun în tumorile profunde de volum mic (1).

Efectele chimioterapiei asupra aspectelor celulare și histologice în GBL sunt puțin cunoscute și încă discutabile. Se consideră că agenții alchilanți produc un beneficiu în 10% din cazuri, toți având o eficacitate similară. Carmustina (BCNU), procarbazina, cisplatinum, lomustina (CCNU), nimustina (ACNU), au fost primii agenți chemoterapeutici utilizați în glioamele maligne. În încercarea de a reduce efectele adverse a chimioterapiei sistemice s-au încercat mai multe metode de a administra cât mai local citostaticul. Administrarea intraarterială de Carmustina a provocat deteriorare vizuală, leucoencefalopatie, toxicitate retiniană etc.

S-a încercat administrarea locală peroperatorie, după excizia cât mai completă a tumorii, de carmustină - gel sau carmustina conținută în așa numiții "biscuiți" - wafers (7,7 mg în 200 mg polifeprosan). Unele studii randomizate au evidențiat că agenții alchilanți aplicați local pot crește supraviețuirea cu 9-13 săptămâni (7). Singurele complicații ale implanturilor cu citostatice constau în: edem cerebral, pot favoriza suprainfecția plăgii operatorii, creșterea incidenței crizelor epileptice, etc.

Temodal-ul (temozolomida) este un alt agent alchilant , derivat de nitrozuree, utilizat ca anti-angiogenetic. Eficacitatea lui a fost pusă la îndoială datorită depresiei leucocitare și trombocitare pe care o produce (8).

Terapia fotodinamică este o terapie bimodală ce implică injectarea preoperatorie a unui compus fotosensibilizant ce se localizează selectiv în celulele tumorale, urmată de excizia chirurgicală standard a tumorii, iar cavitatea restantă este iluminată (iradiată) cu raze laser cu o anumită lungime de undă și care sunt absorbite de celulele tumorale fotosensibilizate. Preparatul folosit este un derivat de hematoporfirină (Photofrin) și se administrează în doza de 5 mg/kgc cu 24 ore preoperator. Durata medie pentru fotoiradiere este de 30-60 minute modificând permanent direcția razei laser pe toată suprafața cavității de rezecție și irigând permanent cu ser pentru a preveni supraîncălzirea excesivă (1). Unele studii au evidențiat o prelungire a supraviețuirii cu cca. 18 săptămâni. Pacienții vor evita expunerea la soare pe o perioadă de 6-8 săptămâni după o astfel de procedură (1).

Excizia chirurgicală a recidivei tumorale poate crește supraviețuirea cu aproximativ 36 de săptămâni, cu mențiunea ca 10% din GBL pot recidiva la distanță de locația inițială (12).

Psihoterapia. Unele studii efectuate asupra profilului psihologic al unor pacienți tratați pentru GBL multiform au arătat că depresia și sentimentul lipsei de speranță de vindecare sunt asociate cu evolutie rapid infaustă, în timp ce comportamentul combativ și optimist este însoțit de rezultate mai bune (6). Datele semnalate sugerează că endorfinele (mediatori biochimici ai emoțiilor), sunt implicate în reglarea imună prin influențarea activităților celulelor "natural killer" (6).

Imunoterapia aplicată în cazul GBL multiforme, după injectarea intraveneoasă sau intracarotidiană de anticorpi monoclonali, produce o acumulare specifică la nivelul tumorii, dar ea este insuficientă pentru obținerea unui efect terapeutic (6). Bariera hematoencefalică poate constitui o piedică pentru pasajul anticorpilor monoclonali.

Încercările de depăşire a acestei piedici au constat în deschiderea barierei hemato-encefalice. Au existat încercări de injectare în restul tumoral, după excizia chirurgicală de limfocite "killer" sensibilizate, dar rezultatele favorabile nu s-au confirmat (2). Administrarea intravenoasă de imunomodulatori de tipul IL2, datorită creşterii edemului cerebral, nu poate constitui un tratament eficace împotriva GBL (6).

Durata medie de supraviețuire după tratament este aproximativ 8 luni (8). Pacienții mai tineri cu GBL secundar prezintă intervale ceva mai mari de supraviețuire, care pot ajunge până la 3-5 ani. Rezultatele tratamentului multimodal în GBL trebuie urmărite continuu clinic (statusul neurologic) şi paraclinic (CT-scan şi RMN repetate), asociate cu examen hematologic şi biologic general (1) (fig. 11).

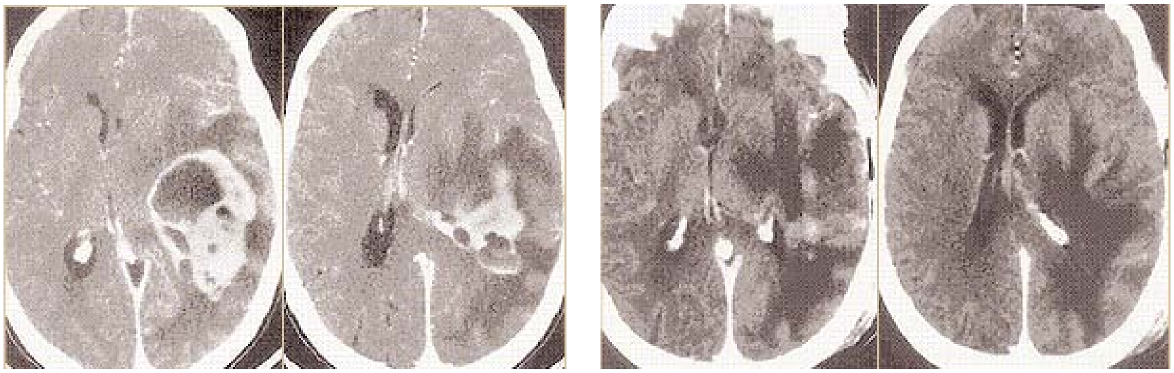

Fig. 11. Aspect pre- şi postopertaor, într-un caz de GBL multiform temporo-parietal stâng;

Cauza decesului provocat de acest tip de tumoră este neclară. Deşi o parte dintre pacienți decedează datorită efectului de masă şi hernierii cerebrale secundare, alții nu prezintă efect de masă semnificativ în momentul decesului (1). Deteriorarea neurologică progresivă şi decesul sunt cauzate de afectarea cerebrală de cauze necunoscute (12).

Concluzii

Diversitatea celulară determină o mare varietate de tipuri şi grade tumorale, care nu sunt uşor de identificat numai pe baza aspectelor histopatologice clasice (10). În plus, tumorile gliale sunt de obicei neomogene, atât în privința gradului tumoral, cât şi al tipului celular. Actul operator aplicat asupra unei tumori localizate intracerebral este autolimitat, fragmentele tumorale sunt, de obicei, mici şi adeseori nereprezentative pentru tipul sau gradul tumoral (7). Din acest motiv, diagnosticul se precizează prin coroborarea obligatorie a aspectelor clinice cu localizarea tumorii şi mai ales cu neuroimagistica (10). Este obligatorie separarea glioamelor de grade inferioare de cele superioare şi mai ales a celor neinfiltrative de cele difuz infiltrative, întrucât atitudinea chirurgicală este diferită de la caz la caz (12).

Astmul bronşic indus de aspirină – o problemă de importanţă practică

Cpt. Dr. Mihăiţă PĂTRĂŞESCU[*]

Astmul bronşic indus de aspirină face parte din triada clasică Samter Vidal alături de polipoza nazală sau rinosinuzita. Este mai degrabă apanajul vârstelor adulte, fiind cel mai adesea o forma severă de astm. Tratamentul de desensibilizare cu aspirină este o alternativă terapeutică la îndemână pentru cazurile în care nu se poate apela la altă clasă de medicamente.

astmul bronşic indus de aspirină

Aspirin induced asthma is a part of the clasic Samter's triad along with nasal poliposis or rhinosinusitis. It is rather encountered in adult ages. It is a severe form of asthma. Desensitisation treatment with aspirin is a good therapeutic alternative to be used whenever another class of drugs aren't handy.

Astmul bronşic cunoaşte o prevalenţă în creştere în întreaga lume, cele mai mari rate fiind descrise în Noua Zeelandă şi Australia (aprox. 10%) . Este definit ca o suferinţă inflamatorie bronşică cronică cu predominenţa eozinofilelor care determină episoade recurente de wheezing, dispnee, senzaţie de constricţie toracică , tuse, în mod particular noaptea sau dimineaţa devreme şi la terminarea efortului fizic. Cel puţin în primele etape de evoluţie obstrucţia bronşică este total reversibilă, spontan, după administrarea unui beta2 agonist inhalator sau după o cură scurtă de corticosteroizi inhalator sau per os.

Caracteristica funcţională ventilatorie a astmului bronşic este hiperreactivitatea bronşică nespecifică la stimuli precum histamina, metacolina, manitolul. Deşi nu este nici suficient de specifică sau sensibilă pentru diagnosticarea astmului totuşi evoluează paralel cu severitatea acestuia şi cu inflamaţia bronşică . Monitorizarea fracţiei oxidului de azot în aerul expirator (FeNO) ca martor indirect al inflamaţiei eozinofilice poate să devină, într-un viitor foarte apropiat, o metodă neinvazivă la îndemână pentru managementul astmului bronşic:

- FeNO creşte înaintea deteriorării controlului astmului precedând modificările spirometrice care, adeseori nu evoluează paralel cu severitatea simptomelor
- FeNO este mult mai mare la pacienţii cu astm bronşic decât în alte suferinţe
- FeNO crescut anunţă responsivitatea la tratamentul corticosteroidian
- Modificări ale FeNO în cursul tratamentului permite ajustări ale acestuia.

În 75% din cazuri astmul bronşic este o problemă alergologică în sensul în care episoadele de bronhospasm pot fi declanşate de expunerea la alergeni specifici repiratori (polen, mucegaiuri, epitelii de pisică, câine, iepure, acarienii din praful de casă). În aceste situaţii poate fi demonstrată existenţa imunoglobulinelor E alergen specifice prin teste cutanate alergologice sau examene serologice. Chiar şi la aceşti pacienţi acţionează factorii declanşatori nespecifici: poluarea aeriană, efortul fizic, infecţiile virale respiratorii, fumul de tutun.

---

[*] Spitalul Clinic de Urgenţă Militar Central Dr. Carol Davila, Cabinet de Alergologie

O clasificare mai veche a astmului bronşic, încă funcțională din considerente didactice, identifică două forme etiologice:

- **astmul extrinsec** (cu referire la majoritatea cazurilor în care se identifică componenta alergică IgE mediată)
- **astmul intrinsec** (în care episoadele bronhospastice nu pot fi puse în asociere cu un alergen față de care să se demonstreze o reactivitate de tip IgE).

Astmul intrinsec este definit pentru întâia oară de Rackemann în 1947 care atrăgea atenția asupra existenței unui subgrup de pacienți adulți care prezentau:

- teste cutanate alergologice negative la majoritatea alergenelor comune
- fără istoric familial de boli atopice
- eozinofilie persistentă
- un curs evolutiv sever (cu spitalizări frecvente, episoade bronhospastice severe şi rezistente la tratament, responsivitate slabă la corticosteroizi)
- fără imbunătățire clinică imediată la internare.

În 1956 Samter adaugă observația că unii pacienți din acest subgrup prezintă:

- polipoză nazală
- sinuzită
- intoleranță la aspirină

Se defineşte astfel **triada Samter-Vidal**, aşa cum va fi cunoscută ulterior, care reuneşte ***polipoza nazală cu astmul bronşic şi intoleranța la aspirină*** . Cele trei elemente nu sunt prezente întotdeauna. Polipoza nazală poate lipsi fiind prezentă doar o rinosinuzită nonpolipoasă. În diagnosticul sinuzitei standardul imagistic de aur este reprezentat de examenul de tomografie computerizată iar nu de radiografia simplă a sinusurilor paranazale .

Din cele prezentate până acum se impun câteva precizări:

1. inflamația eozinofilică bronşică nu se întâlneşte exclusiv în astmul alergic (ea este prezentă şi astmul cu intoleranță la aspirină)
2. numărul eozinofilelor în sputa indusă se corelează cu FeNO şi cu şansa unui răspuns pozitiv la tratamentul antiinflamator corticosteroidian
3. predominența neutrofilelor în inflamația bronşică (forme de astm severe, astm cu crize bronhospastice predominent nocturne etc) se asociază cu un răspuns mai slab la corticosteroizi
4. polipoza nazală la un pacient astmatic impune explorarea toleranței la aspirină
5. indiferent de factorul cauzal şi de factorii declanşatori ai crizelor, inflamația bronşică în astm este persistentă cu evoluție şi în afara episoadelor de acutizare.

Acidul acetilsalicilic (aspirina) este utilizat în terapeutica umană de mai mult de 100 de ani. Împreună cu alte antiinflamatorii nesteroidiene (AINS) îşi exercită efectele antiinflamtorii, analgezice şi antipiretice (dar şi o parte din efectele adverse) prin inhibiția ciclooxigenazelor (COX1 şi COX2). AINS-urile induc o serie de efecte adverse printre care se numără şi cele din tabelul 1.

TABEL 1

Efecte adverse induse de Aspirină/AINS
Gastrită Ulcer gastroduodenal Hepatotoxicitate Anemie Trombocitopenie Anomalii de coagulare Nefrită interstiţială Sindrom Stevens-Johnson Eritem fix medicamentos Necroliză epidermică toxică Eritem nodos Erupţii maculopapulare Vasculită leucocitoclastică

În septembrie 2001 Stevenson publică în Annals of Allergy Asthma and Immunology o clasificare a reacţiilor allergice şi pseudoalergice la aspirină/AINS într-o încercare de sistematizare bazată pe posibile mecanisme. Primele patru tipuri de reacţii sunt legate de inhibiţia COX1, fiind astfel comune tuturor AINS. Ultimele patru tipuri cunosc o mediere imună şi, prin urmare, nu sunt reacţii adverse de clasă ci medicament specifice.

TABEL 2 *CLASIFICAREA STEVENSON A REACŢIILOR ALERGICE ŞI PSEUDOALERGICE LA ASPIRINĂ/AINS*

Tip de reacţie	**Caracteristici**
Tipul 1: astmul şi rinita la AINS induse la pacienţii astmatici	-Un subset de pacienţi astmatici prezintă la ingestia de AINS, crossreactiv, o combinaţie de rinoree, obstrucţie nazală, hiperemie conjunctivală, edem periorbital, bronhospasm -reacţia este doză dependentă
Tipul 2: urticaria şi angioedemul induse de AINS la pacienţii cu urticarie cronică	-apare mai frecvent la cei cu urticarie cronică activă -reacţia este doză dependentă
Tipul 3: urticaria şi angioedemul induse de AINS la indivizi normali	-apare, de asemenea, crossreactiv la AINS -unii pacienţi vor dezvolta urticarie cronică idiopatică ulterior
Tipul 4: reacţii mixte la indivizi normali	-cuprinde caracteristici din tipurile precedente
Tipul 5: urticarie şi angioedem induse de un singur AINS la indivizi normali	-crossreactivitatea AINS nu apare -atopia pare a fi un factor de risc
Tipul 6: anafilaxie indusă de un singur AINS	-de asemenea crossreactivitatea AINS nu se întâlneşte -demonstrarea IgE specifice pentru un singur AINS este dificil de demonstrat
Tipul 7: menigită aseptică la un singur AINS	-este un diagnostic de excludere -descris la naproxen, sulindac, tolmentin şi ibuprofen
Tipul 8: pneumonita de hipersensibilizare la un singur AINS	-nu a fost descrisă pentru aspirină.

Deci:

- pentru primele patru tipuri de reacţii mecanismul posibil incriminat este cel legat de inhibiţia COX1 ; din acest motiv reacţiile apar crossreactiv la toate AINS care inhibă această enzimă
- pentru primele patru tipuri de reacţii nu este necesară existenţa unei sensibilizări anterioare; reacţiile sunt doză dependente
- pentru ultimele patru tipuri de reacţii existenţa unui posibil mecanism imun face ca reacţia încrucişată între mai multe AINS bazată pe inhibiţia comună a COX1 să nu existe; aceste reacţii sunt medicament specifice şi nu sunt doză dependente.

Astmul bronşic indus de aspirină

Termenul de „indus" este impropriu câtă vreme intoleranța la aspirină apare la pacienții care suferă, deja, de astm bronşic. Actual se vorbeşte, astfel, de ***Boală respiratorie exacerbată de aspirină (AERD).*** Prevalența pare să fie mai mare la sexul feminin (2,3 / 1 feminin/masculin) iar debutul tinde să fie mai precoce iar severitatea bolii mai mare. Atopia nu este un factor de risc dar 1/3 din pacienți sunt atopici iar un istoric familial de AERD este prezent la 6% din bolnavi.

Prevalența AERD bazată doar pe istoricul pacienților este de aproximativ 10% printre pacienții astmatici peste vârsta de 10 ani. Dacă se ia în considerare un test de provocare orală, se ajunge la 20%. La subpopulația astmatică care asociază polipoza nazală sau rinosinuzita chiar fără un istoric personal de reactivitate la aspirină prevalența creşte la 40% dacă se efectuează teste de provocare orală. Dacă există, însă, un istoric personal de simptome respiratorii la expunerea la aspirină testul de provocare orală este pozitiv în peste 80% din cazuri.

Populația pediatrică sub vârsta de 10 ani are rar AERD.

De asemenea astmul bronşic şi urticaria declanşate de expunerea la aspirină se asociează rar la acelaşi individ.

Intoleranța la aspirină survine de obicei după o perioadă evolutivă de luni sau ani a patologiei respiratorii superioare (rinitosinuzită, polipoză nazală) şi inferioare (astm bronşic).

Administrarea de aspirină la un pacient astmatic nu este considerată un factor de risc pentru dezvoltarea de novo a intoleranței la aspirină.

Evitarea expunerii la aspirină/AINS nu modifică cursul bolii respiratorii, procesul inflamator cronic neputând fi în acest fel modificat.

Scurtă incursiune în patogeneza AERD

Semnele şi simptomele datorate expunerii acestor pacienți la aspirină şi alte AINS sunt în strânsă legătură cu interceptarea căilor de metabolizare ale acidului arahidonic. Inhibiția căii ciclooxigenazelor favorizează calea 5 lipooxigenazei (5 LO) cu producția în exces de leucotriene .

La pacienții cu AERD s-a observat:

- deficit constituțional al prostglandinei E2 (care inhibă 5 LO şi contrabalansează efectele negative ale leucotrienelor- LT)
- exces funcțional al LTC4 sintetazei
- nivele crescute bazal ale LTC4 în sânge şi lichidul de lavaj bronşic
- nivele crescute bazal şi după test de provocare orală cu aspirină ale LTE4 în urină
- nivele scăzute ale lipoxinei (mediator antiinflamator rezultat în urma metabolizării acidului arahidonic)
- producție crescută de acid 15 hidroxieicosatetraenoic (15 HETE) la stimularea in vitro a celulelor epiteliale ale polipilor nazali cu aspirină (această observație stă la baza unui test diagnostic in vitro numit ASPIT – aspirin sensitive patient identification test)
- diminuarea apoptozei eozinofilelor implicate în inflamația bronşică şi nazală.

LTC4 determină bronhospasm, creşterea permeabilității capilare cu edem, chemotaxie eozinofilică, creşterea producției de mucus.

Diagosticul AERD

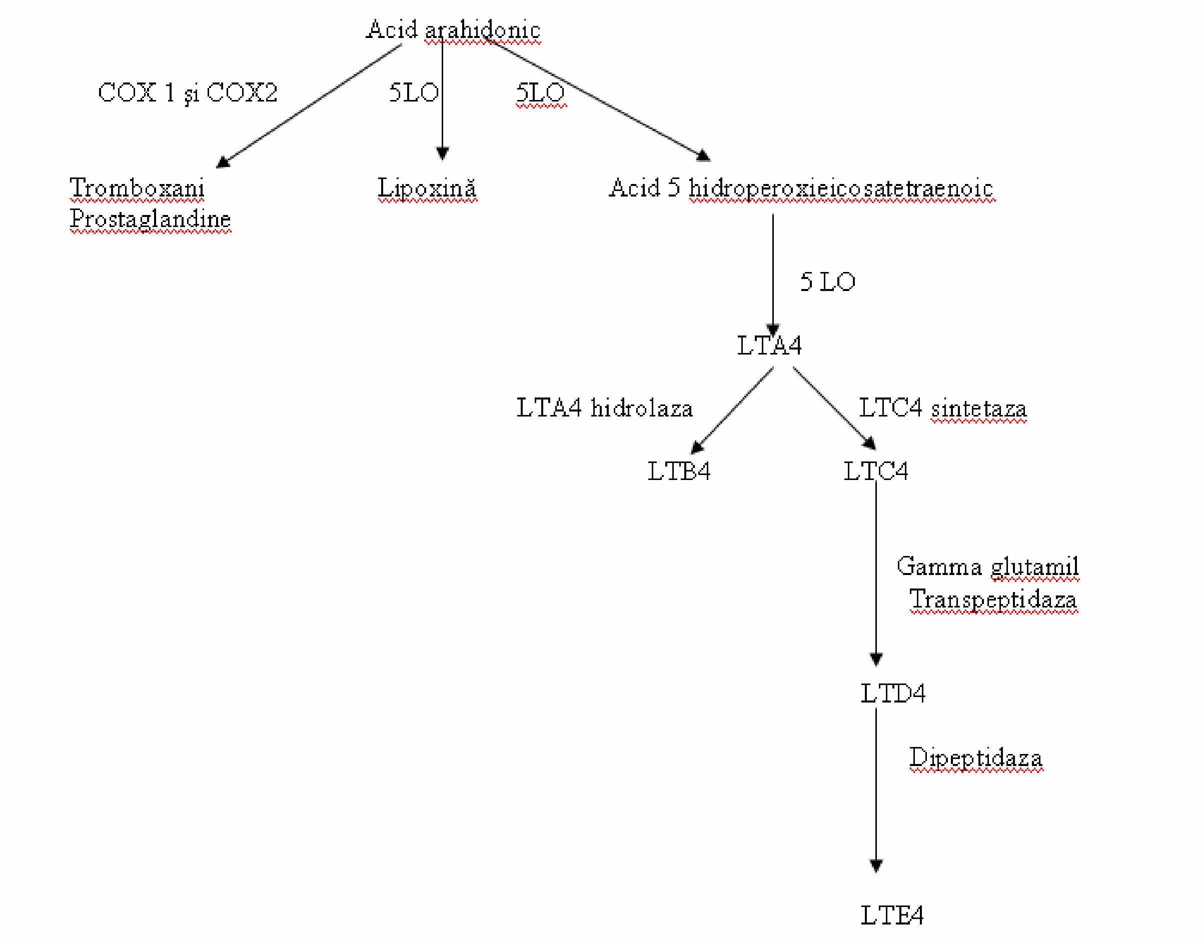
Documentarea intoleranței la aspirină şi la alte AINS se face printr-un protocol de provocare orală cu doze progresiv crescătoare administrate la intervale de 2 ore. Protocolul se desfăşoară pe o perioadă de 2 zile. Testul este negativ dacă la 2 ore după doza de 650mg aspirină nu apar simptome rinobronşice. Testul este considerat pozitiv la o scădere a VEMS cu 20% sau dacă apare rinoree/obstrucție nazală.

TABEL 3 PROTOCOL DE PROVOCARE ORALĂ PENTRU AERD

Doza de aspirină (mg)			
Timp	**ziua 1**	**ziua 2**	**ziua 3**
7 a.m.	Placebo	30	100-150
10 a.m.	Placebo	45-60	150-325
1 p.m.	Placebo	60-100	650

Contraindicațiile testului de provocare orală sunt:
- istoric de reacții anafilactice severe precipitate de aspirină sau alt AINS
- boli severe cardiace, digestive, hepatice, renale
- infecții de tract respirator în intervalul a 4 săptămâni anterior testării
- sarcină
- tratament cu betablocante

Trebuie menționat faptul că adminstrarea anterioară testului de provocare oral cu aspirină a mai mult de 10 mg prednison sau a unui inhibitor de receptori de leucotriene poate bloca o reacție pozitivă.



Acid arahidonic
COX 1 şi COX2

LTC4 sintetaza
LTB4
LTC4
Gamma glutamil
Transpeptidaza
LTD4
Dipeptidaza
LTE4

Tratament

Tratamentul AERD vizează în primul rând boala de bază : astmul bronşic si rinosinuzita.

Evitarea aspirinei dar şi a AINS neselective sau parţial selective este un gest imperativ.

Pacienţii cu AERD pot tolera inhibitori înalt selectivi de COX2 precum celecoxib sau etoricoxib.

Tratamentul de desensibilizare prin administrarea de doze progresiv crescătoare de aspirină până la doza terapeutică urmată de administrarea regulată a acesteia se poate face, fiind , însă, grevat de riscul efectelor adverse ale unei terapii cu AINS de lungă durată. ***Întreruperea aspirinei pentru o perioadă mai mare de 5 zile duce la reapariția intoleranței***. ***Desensibilizarea are caracter încrucişat putându-se efectua cu aspirină pentru toate celelalte AINS.***

În încheiere accentuez asupra necesităţii diagnosticării AERD, suspiciunea existenței intoleranței la aspirină/AINS fiind legată de existența unui astm sever, greu controlabil medicamentos asociat polipozei nazale sau rinosinuzitei.

OBIECTIV: Pancreatita acută rămâne o afecţiune cu prognostic incert cu toate cuceririle în domeniul diagnosticului şi tratamentului. Obiectivele care au stat la baza acestui studiu desfăşurat pe o perioadă de 13 ani au fost acelea de a constata şi de a evalua dificultăţile diagnostice în pancreatita acută.

MATERIAL ŞI METODĂ: Studiul a inclus 182 de pacienţi, strategia diagnostică implicând determinarea unui diagnostic pozitiv la internare urmată de determinarea diagnosticului de gravitate; acestea au fost completate cu datele imagistice, pentru ca în final să tentăm determinarea unui diagnostic etiologic.

CONCLUZIE: Determinarea cu acurateţe a unui diagnostic de pancreatită acută permite un abord terapeutic adecvat, centrat pe gravitatea bolii.

---

pancreatita acută **diagnostic** **explorări imagistice**

ABSTRACT

Acute pancreatitis remains a diasease with bad prognosis, even diagnosis and treatment gains many advances. The aim of this study achieved on a period of 13 years was to evaluate the diagnostic difficulties in acute pancreatitis. We included in this study 182 patients, diagnostic strategy involving a good diagnosis at the admission followed by the severity diagnosis and completed by the imagery. Etiological diagnosis was tented for everyone. Results were shown on detail. We concluded that a good diagnosis assure a correct treatment for the severity of disease.

Key words: acute pancreatitis, diagnosis, imaging examens

INTRODUCERE

Pancreatita acută este o afecţiune severă în al cărei management sunt implicaţi, în diverse etape, chirurgi, internişti, gastroenterologi, medici care îşi desfăşoară activitatea în medicina de urgenţă, chiar medici de familie. De la prima descriere anatomoclinică de către Reginald Fitz (1889), pancreatita acută rămâne o afecţiune cu prognostic incert, distingându-se forme edematoase cu evoluţie benignă şi vindecare spontană şi forme necrotico-hemoragice, forme grave, a căror evoluţie rămâne totdeauna incertă (1). Debutează prin activarea prematură a zimogenelor intracelulare, inducţia factorilor de transcripţie, factorul nuclear kB (NF-kB) şi activatorul proteic 1 (AP-1), cu generare locală de cytokine şi chemokine.

Acestea conduc la inflamaţie şi leziuni celulare locale şi generale cu posibilă evoluţie spre insuficienţă multiorganică şi deces. Eliberarea citokinelor şi a altor mediatori proinflamatori reprezintă determinantul major al insuficienţei organice şi a mortalităţii precoce (2).

Diagnosticul pancreatitei acute se bazează pe manifestările clinice şi pe rezultatele unor teste biochimice, dar acestea sunt numai câteva criterii din lungul şir de elemente de diagnostic ale acestei afecţiuni (3). Un studiu prospectiv multicentric realizat de AURC şi ARC, citat de Faginez (4) şi efectuat în Franţa arată că 4% dintre sindroamele dureroase acute ale abdomenului observate în cursul a 7 zile corespund unei pancreatite acute.

Tehnicile imagistice au ameliorat sensibil diagnosticul, scorurile clinice de diagnostic şi gravitate a bolii fiind îmbunătăţite prin implicarea ecografiei, computer tomografiei (CT), rezonanţei magnetice nucleare (RMN) etc. Introducerea CT ca metodă diagnostică standard pentru detectarea timpurie a necrozei a permis o înţelegere mai bună a relaţiei dintre modificările morfopatologice din pancreas şi evoluţia naturală a bolii (5).

Scopul studiului nostru a fost acela de a evalua dificultăţile diagnostice din pancreatita acută şi de a evidenţia rolul diagnostic major al computer tomografiei ca metodă imagistică de diagnostic, stadializare şi urmărire evolutivă.

MATERIAL ŞI METODĂ

Evaluarea s-a efectuat, retrospectiv, pe durata a 13 ani (ianuarie 1995-decembrie 2007) şi a inclus un număr de 211 pacienţi cu pancreatită acută internaţi în Clinica de Chirurgie a Spitalului Clinic de Urgenţă Militar din Craiova. Foile de observaţie ale tuturor pacienţilor incluşi în studiul nostru au fost evaluate, extrăgându-se elementele care au stat la baza diagnosticului de pancreatită acută. Strategia diagnostică, aşa cum a fost iniţiată încă de la internarea primului pacient, a parcurs stabilirea diagnosticului pozitiv pe baza datelor clinice coroborate cu câteva explorări paraclinice, urmată de stabilirea diagnosticului de gravitate pe baza unor criterii, în primul rând, bioclinice, urmărite în evoluţia primelor 24-48 de ore. Etapa diagnosticului imagistic a adus informaţii legate de distrugerea structurii pancreatice, devenind operativă după 4-7 zile de la debutul bolii. Supravegherea ulterioară, bioclinică şi imagistică a evoluţiei pancreatitei acute a impus strategia terapeutică. Diagnosticul etiologic s-a constituit într-un alt important factor de decizie a secvenţialităţii terapeutice medico-chirurgicale după stingerea puseului acut.

Trebuie remarcat faptul că tomografia computerizată a devenit un element extrem de important de diagnostic odată cu acumularea experienţei în domeniu, această tehnică imagistică fiind folosită şi cu rol de evaluare a evoluţiei bolii. Nicio altă explorare imagistică utilizată (cu referire la ecografia abdominală şi, atunci când a fost disponibilă, la rezonanţa magnetică nucleară) nu şi-a dovedit o eficienţă superioară acesteia. În cazul ecografiei am constatat adesea dificultăţi de descriere a pancreasului în contextul meteorismului abdominal din cadrul bolii, RMN fiind mai greu accesibilă, dar şi mai scumpă comparativ cu CT. În aceste condiţii am apreciat raportul calitate-preţ ca fiind adecvat pentru CT.

REZULTATE

Lotul de pacienţi studiaţi a fost alcătuit din 132 bărbaţi şi 79 femei, 101 provenind din mediul urban, iar 110 din mediul rural. Vârsta medie a fost de 59 de ani (cu limite între 18 şi 82 de ani, decadele cu incidenţă maximă fiind 41-50 de ani, urmată de aproape de decadele 51-60 şi 61-70 de ani.

În studiul nostru am constatat că profilul clinic al afecţiunii se evidenţiază conform cu cunoştinţele clasice, pancreatita acută fiind un sindrom dureros abdominal brutal, cu iradiere posterioară, decalaj termic, amestec de semne de ocluzie şi peritoneale şi o tendinţă de colaps cardiovascular.

În 2/3 din cazuri dozarea amilazemiei a constatat cifre superioare (de 4 ori normalul), aceste informaţii simple culese în urgenţă permiţând un diagnostic de certitudine.

În 1/3 din cazuri diagnosticul a fost de prezumţie, adesea prin eliminarea unor sindroame acute abdominale, în aceste cazuri fiind necesară lărgirea investigaţiilor biologice (amilazurie, lipazemie, leucocitoză, calcemie) completată cu alte mijloace diagnostice (scanner-ul abdominal, puncţia-lavaj a peritoneului şi laparotomia diagnostică).

Astfel, studiind datele clinice, am constatat prezenţa sindromului dureros acut abdominal tipic la 66,5% dintre pacienţi şi atipic la 33,5%. Alte date clinice semnificative statistic constatate sunt: alterarea stării generale (51,2%), sindromul ocluziv caracterizat de vărsături, meteorism abdominal şi oprirea tranzitului (42,5%), apărarea musculară localizată (48,2%) ori difuză (18,7%), diferite tulburări cardiovasculare (59,6%), acestea din urmă împreună cu oligoanuria, polipneea şi sindromul icteric constituindu-se într-o simptomatologie ce traduce insuficienţa de organ şi definind gravitatea bolii încă de la debut.

Elementele biologice caracteristice ce au susţinut diagnosticul au fost leucocitoza (71,5%), hiperamilazemia-amilazurie (39,4%), creşterea bilirubinei (22,3%), hiperglicemia (31,6%). Acestea au fost coroborate cu date clinice în cadrul indicilor bioclinici de gravitate a bolii.

La examenul radiologic simplu (abdominal şi toracic), utilizat de rutină, s-au constatat elemente semnificative în 6,7% din cazuri – ansa sentinelă în 5,6% din cazuri şi reacţie lichidiană pleurală stângă în 3,8% din cazuri – dar a permis excluderea altor sindroame acute abdominale.

Ecografia abdominală s-a efectuat de rutină, dar rezultatele au fost adesea parazitate de meteorismul abdominal. Utilitatea sa a fost efectivă în cazul etiologiei biliare şi pentru diagnosticul colecistitei acute ori a colecţiilor abdominale.

Pentru aprecierea gravităţii bolii am utilizat indici prognostici, bioclinici, peritoneali ori computer-tomografici (Imrie, Ranson, APACHE şi Balthazar). Conform acestora am încadrat cazurile ca pancreatite acute grave la 87 de pacienţi (41,2%) şi uşoare ori medii la 124 de pacienţi (58,8%).

Compararea datelor CT şi a datelor bioclinice a dat, uneori, rezultate divergente. CT nu este superioară testelor bioclinice; în schimb, rezultatul examinării iniţiale prezintă interesul furnizării unui document de referinţă susceptibil de a fi comparat cu examinările CT ulterioare pentru supravegherea evoluţiei şi stabilirea indicaţiei terapeutice.

S-a practicat tomografia computerizată în 88 de cazuri: la internare (19 pacienţi), după o zi la 21 de pacienţi, după 4 zile la 18 pacienţi, după 7 zile în 14 cazuri, postoperator (16 cazuri) şi repetat la 36 de pacienţi. Încadrarea conform clasificării Balthazar a fost următoarea: gradul A – 18 cazuri (20,4%), B la 11 cazuri (12,5%), C în 22 de cazuri (25%) (Fig.1), D la 26 de pacienţi (29,5%) şi E la 11 cazuri (12,5%) (Fig. 2, 3 şi 4).

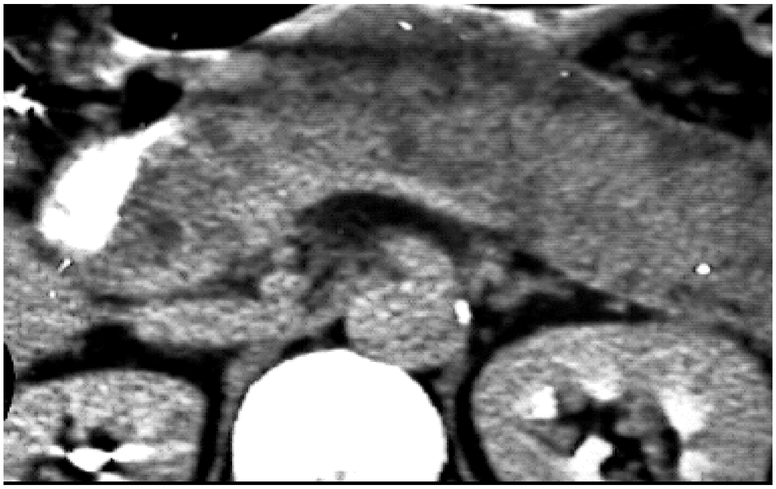

Fig.1. Pancres cu colecţie minimă peripancreatică şi zone minime de necroză. Scor Balthazar C

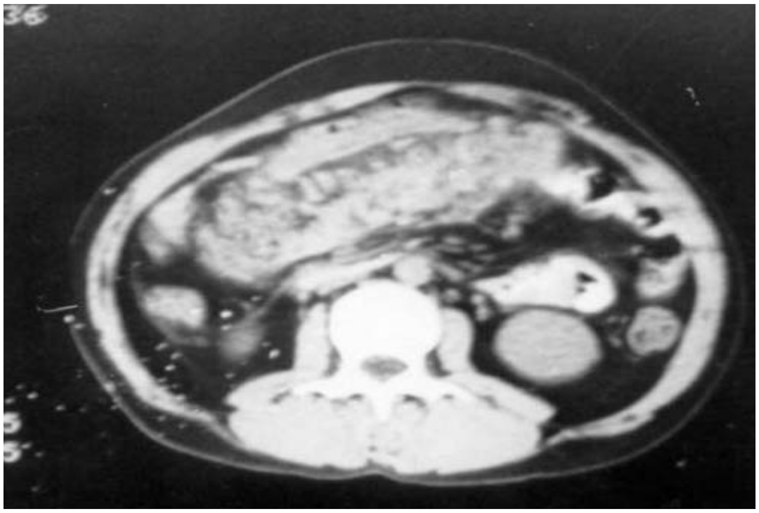

Fig.2. Pancreatită acută necrotico-hemoragică. Scor Balthazar E

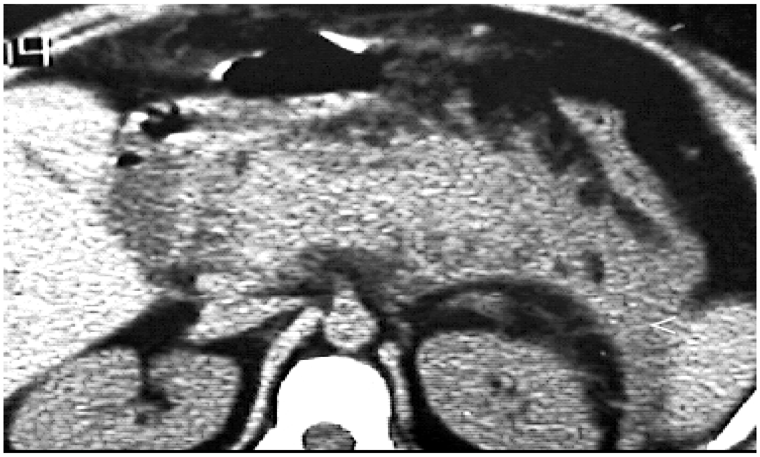

Fig.3. Pancreatită necrotică: pancreas cu zone de necroză cu fuzee peripancreatice, anterior şi pararenal stâng; semnul "haloului". Scor Balthazar E

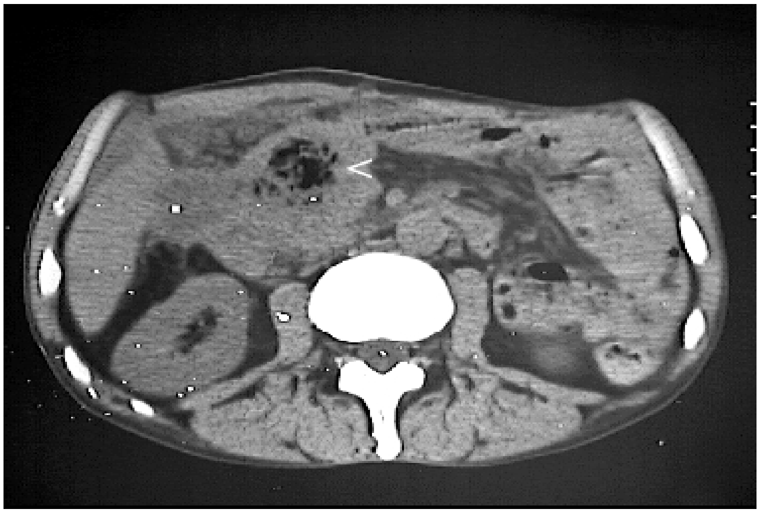

Fig.4. Necroză infectată – colecție fluidă cu pereți groşi contur difuz şi bule de gaz. Abces pancreatic infracefalic. Scor Balthazar E

Din punct de vedere etiologic am constatat etiologia biliară la 36,5% dintre pacienţi, alcoolică la 39,2%, pancreatita acută recurentă constatându-se la 54 de pacienţi (25,6%).

Diagnosticul de necroză infectată a avut la bază mai multe criterii: clinice (sindrom infecţios), biologice (leucocitoză), computer-tomografice (bule gazoase), puncţie eco-ghidată şi datele constatate intraoperator (aspecte macroscopice) (Fig. 5). Bacteriologia pozitivă s-a constatat la 41 de pacienţi (19,4%) prin prelevări intraoperatorii, *E.coli* fiind cel mai frecvent agent patogen (26%), urmat de *Enterococcus*, *Klebsiella*, *Enterobacter* şi stafilococ, fungii fiind descoperiţi izolat.

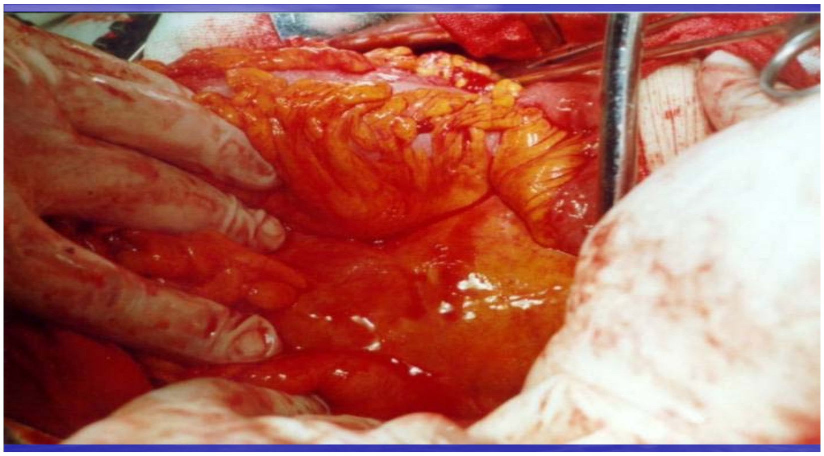

Fig.5. Pancreatită acută – fuzee de citosteatonecroză. Aspect intraoperator

DISCUŢII

Pancreatita acută rămâne una dintre marile probleme insuficient cunoscute datorită frecvenţei sale relative în chirurgia abdominală de urgenţă, dificultăţilor de diagnostic şi mai ales terapeutice ale căror principii comportă încă discuţii şi mortalitate crescută în formele severe. Mortalitatea generală a bolii variază între 2,1-7,8% (6). Evoluţia bolii este determinată de doi factori care reflectă severitatea acesteia: insuficienţa de organ şi necroza pancreatică. În general, decesul prin pancreatită acută severă se produce în primele două săptămâni. Mortalitatea tardivă se datorează infecţiilor, în particular infectării necrozelor pancreatice. Studii recente au demonstrat statistic reducerea mortalităţii în ultima perioadă ca rezultat al tratamentului intensiv modern (7).

Din punctul de vedere al strategiei diagnostice, cel mai important lucru la internarea bolnavului în spital este stabilirea diagnosticului pozitiv de pancreatită acută şi, apoi, în primele 24-48 de ore, a celui de gravitate (8). În experienţa noastră, diagnosticul pozitiv a fost posibil şi corect de la început la 69,78% dintre pacienţi, bazându-ne pe tabloul clinic caracteristic ori mai puţin specific, sprijinit de câteva explorări paraclinice: valori crescute ale amilazemiei, amilazuriei, leucocitozei, proteinei C reactive şi altele mai puţin semnificative (hiperglicemie, hiperbilirubinemie). Investigaţiile imagistice sunt nespecifice în primele 24-48 de ore (5).

Diagnosticul de gravitate se sprijină, în primul rând, pe criterii bioclinice (Ranson, Imrie ori APACHE), dar şi pe dozarea unor markeri ca lipazemia, proteina C reactivă, procalcitonina (8). Criteriile morfologice stabilite pe baza imaginilor computer-tomografice au permis o nouă clasificare a pancreatitelor acute şi încadrarea lor în forme uşoare-medii şi grave. CT permite, de asemenea, supravegherea evoluţiei colecţiilor, cercetarea gazelor (semne de infecţie a necrozei) în spaţiile retroperitoneale şi vizualizarea unui abces pelvin (9).

Există studii care arată superioritatea scorului Balthazar în faţa scorurilor bioclinice (10,11). Experienţa noastră confirmă faptul că nu există totdeauna o corelaţie absolută între clasa Balthazar D şi E cu un scor bioclinic Glasgow peste 3 (12).

Invers, un astfel de scor a fost totdeauna în concordanţă cu clasa D şi E Balthazar. Subliniem, în schimb, că întinderea necrozei este proporţională cu mortalitatea, dar trebuie făcută distincţie între necroza infectată şi abces. Intervenţiile chirurgicale asupra necrozelor sterile sunt discutabile (13,14).

CONCLUZII

1. Pancreatita acută este o boală relativ frecventă, diagnosticul său fiind dificil. Problema diagnostică impune, încă de la primirea pacientului, o strategie care să stabilească diagnosticul pozitiv de pancreatită acută, gravitatea acesteia, etiologia, iar în cazul formelor necrotice, dacă necroza este sterilă sau infectată.
2. Diagnosticul pozitiv iniţial depinde, în principal, de o anamneză precisă şi, în egală măsură, de un examen clinic îngrijit, sprijinit de câteva date de laborator simple (amilazemie, amilazurie, leucocitoză) şi completat cu o eventuală puncţie-lavaj peritoneală ori laparoscopie.
3. Diagnosticul formelor grave trebuie stabilit concomitent cu cel pozitiv ori în primele 24-48 de ore şi se sprijină pe existenţa scorurilor bioclinice, a insuficienţei de organ şi pe datele computer-tomografice, strategia terapeutică fiind subordonată gravităţii pancreatitei acute şi evoluţiei sale naturale.

TUMORĂ RENALĂ STÂNGĂ CU INVAZIE ÎN MEZOCOLON ŞI COLONUL DESCENDENT

Mr. dr. Ovidiu C. PACU*, asist. univ. dr. Victor L. MĂDAN,
lt. dr. Ovidiu G. BRATU, lt. dr. Florin I. RUSU, dr. Cristian P. ILIE,
col. conf. univ. dr. Dan L. MISCHIANU

Scop: evidențierea debutului atipic al unei tumori renale şi necesitatea cunoaşterii colectomiei în chirurgia rinichiului tumoral.
Material şi metodă: prezentare de caz clinic de tumoră renală cu debut atipic la care nefrectomia radicală a impus colectomie segmentară datorită invaziei colonului descendent.
Discuții şi concluzii:

- **Varicocelul apărut brusc poate fi primul semn în tumora renală stângă**
- **Chirurgia rinichiului tumoral impune uneori colectomia segmentară „de urgență”**
- **Computer tomograful orientează asupra posibilei extensii locale a suferinței tumorale dar aspectul intraoperator este definitoriu.**

tumoră renală, colectomie, tratament chirurgical

---

tumora renală colectomie tratament chirurgical

Objective: describing acute onset of a renal tumor and the necessity of applying colectomy in renal tumor surgery
Material and method: case report of a renal tumor with uncommon onset in which radical nephrectomy have imposed segmentary colectomy due to descent colon tumoral invasion
Discusions and conclusions:

- varicocele with acute onset can be the first sign in left renal tumor
- renal tumor surgery may impose in some cases segmentary colectomy
- computer tomography shows the possibility of local extension of the tumor, but intraoperatory aspect is decisive.

Keywords: renal tumor, colectomy, surgical treatment

INTRODUCERE

Carcinomul renal tip Grawitz este tumora întâlnită cu frecvență maximă în decadele 5 şi 6 fiind de două ori mai frecventă la bărbați decât la femei. Cele mai frecvente manifestări clinice se grupează într-o triadă caracteristică reprezentată de durere, hematurie şi tumoră renală palpabilă. În afara simtomatologiei clasice este de reținut faptul că tumorile renale se pot manifesta prin semne, simptome şi sindroame extrem de variate, foarte multe fără legătură cu aparatul urinar. Dintre acestea varicocelul simptomatic secundar obstrucției venei spermatice poate apărea ca prim semn clinic. Tratamentul carcinomului renal parenchimatos este eminamente chirurgical şi constă în nefrectomia radicală perifascială.

PREZENTARE CAZ CLINIC

Pacientul MN în vârstă de 53 ani, fumător, din mediu rural, fără antecedente personale patologice notabile se prezintă în Clinica de Urologie pentru mărire de volum şi jenă la nivelul hemiscrotului stâng apărute relativ brusc. Examenul obiectiv evidenţiază prezenţa unui varicocel stâng. Examenele de laborator în limite normale cu excepţia VSH-ului crescut. Este operat prin abord inghinal practicându-se ligatura venelor spermatice dilatate (procedeu Palomo). Evoluţia postoperatorie a fost simplă fiind externat vindecat chirurgical.

La aproximativ 30 zile de la externare pacientul prezintă brusc dureri colicative lombare stângi însoţite de hematurie macroscopică cu cheaguri motiv pentru care se prezintă în clinică pentru investigaţii şi tratament. Examenele de laborator evidenţiază patologic VSH crescut, hematurie microscopică. Ecografia arată prezenţa la nivelul rinichiului stâng, în treimea inferioară, a unei formaţiuni cu contur neregulat, neomogenă, cu diametrul 103/102 mm, vascularizată la examenul Doppler color, fără adenopatii subdiafragmatice. Radiografia pulmonară fără modificări patologice.
RRVS (fig.1) normală iar UIV (fig.2,3) evidenţiază absenţa secreţiei şi excreţiei rinichiului stâng (rinichi stâng mut urografic).

Fig.1 RRVS fără imagini de calculi radioopaci
Fig.2,3 absenţa secreţiei şi excreţei renale stângi – aspect urografic la 15 şi 60 de minute

Examenul CT (fig. 4,5,6) notează existenţa la nivelul rinichiului stâng a unei formaţi tumorale voluminoase de 11/10 cm ce deformează conturul renal în special în jumătatea inferioară, fascia renală îngroşată şi cu contur neregulat spre grăsimea din jur; nu se remarcă modificări de calibru ale lumenului venelor renale stângă şi cavă inferioară, nu se evidenţiază adenopatii locoregionale. Nu sunt prezente alte elemente de patologie a organelor din jurul rinichiului tumoral.

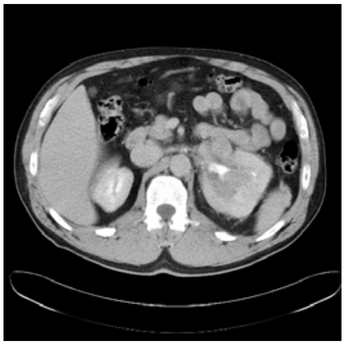

Fig. 4

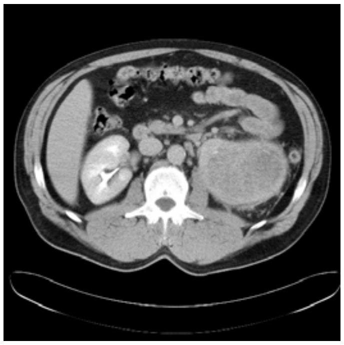

Fig. 5

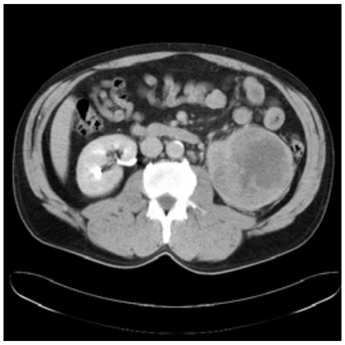

Fig. 6

Fig. 4,5,6 aspecte CT cu substanţă de contrast ale rinichiului tumoral

Se decide intervenția chirurgicală – nefrectomie stângă radicala perifascială prin abord anterior transperitoneal. Intraoperator se evidențiază o tumoră renală de aproximativ 10 cm în diametru ce infiltrează mezocolonul şi colonul descendent sub flexura splenică. S-a practicat extirparea în bloc a rinichiului tumoral împreună cu țesut celulogrăsos inclus în fascia lui Gerota, suprarenala stângă şi a mezocolonului şi colonului descendent interesat tumoral cu limită de siguranță, urmată de colorafie termino-terminală în dublu strat. S-au plasat tuburi de drenaj în loja renală, perianastomotic şi în fundul de sac Douglas. Evoluția postoperatorie a fost lent favorabilă cu reluarea tranzitului intestinal şi pentru gaze la aproximativ 5 zile postoperator.

În ziua a-12-a postoperator pe tubul de dren lombar se exteriorizează un lichid maroniu cu aspect fecaloid. Având în vedere starea generală bună a bolnavului şi prezența tranzitului intestinal pentru materii fecale şi gaze s-a decis tratamentul conservator al fistulei anastomotice cu suprimarea tubului de dren când acesta a devenit ineficient. Pacientul fiind externat vindecat chirurgical.

Examenul histopatologic – carcinom renal cu celule clare, multicentric grad I-II invaziv în grăsimea renală, seroasa şi musculara colonului şi în mezocolonul descendent.

Discuții şi concluzii:

- Varicocelul **stâng** apărut brusc poate fi prima manifestare a unei tumori renale iar examenul ecografic este absolut necesar în protocolul de investigații al varicocelului.
- Examenul CT orientează asupra extensiei locale tumorale dar aspectul intraoperator al leziunii este definitoriu şi poate modifica major intervenția chirurgicală propusă inițial.
- Decizia de a efectua colectomia a fost luată intraoperator fără să existe o pregătire preoperatorie a colonului şi de aceea colectomia segmentară „de urgență” trebuie bine cunoscută de orice urolog care abordează patologia chirurgicală tumorală renală.
- În cazul tumorilor renale mari pacientul trebuie informat (chiar în absența unor semne imagistice) despre posibilitatea existenței unei extensii locale care ar putea impune colectomia segmentară cu colorafie termino-terminală sau colostomie temporară (greu de acceptat de către bolnav).

NEUROFIBROM INTRATORACIC GIGANT DE NERV VAG

Dr. GROZAVU C[*]., dr. ILIAS M,
dr. AURORA FERA, dr. CORNECI

INTRODUCERE:

Deşi tumorile neurogene reprezintă cele mai frecvente tumori dezvoltate la nivelul mediastinului posterior, tumorile neurogene dezvoltate din nervul vag sunt foarte rare. Prezentăm cazul unui pacient în vârstă de 61 de ani internat în Clinica noastră cu diagnosticul de tumora pulmonara dreapta. Intraoperator s-a infirmat apartenența pulmonara a tumorii şi s-a constatat apartenența tumorii de nervul vag drept. S-a practicat excizia completa a tumorii, rezecția nervului vag şi esomiomectomie extramucoasa. Examen histopatologic: neurofibrom.

PREZENTARE DE CAZ

Pacientul in vârsta de 61 de ani se internează în clinica noastră cu diagnosticul de tumora pulmonara dreapta , diagnostic stabilit in urma efectuării unei radiografii toracice şi a examenului computer tomograf toracic. La internare prezintă dispnee la eforturi medii, tuse iritativă. Analizele hematologice au evidențiat: hemograma cu uşoara anemie (Hb=10,9g/dl), biochimie şi coagulograma în limite normale.

Examenul cardiologic stabileşte diagnosticul de cardiopatie ischemica silențioasă.

Probele funcționale ventilatorii externe au arătat disfuncție ventilatorie medie , cu reducerea VEMS cu 24%.

Radiografia toracică în incidență anteroposterioară şi de profil drept a evidențiat opacitate de intensitate subcostală, relativ bine delimitata, cu contur net ce ocupa jumătatea superioară a hemitoracelui drept (fig 1)

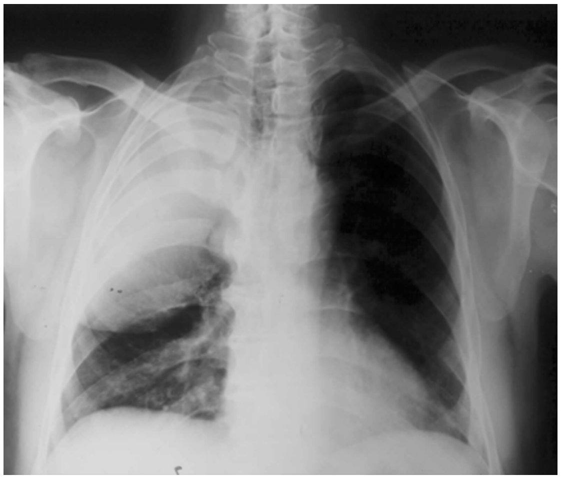

Fig.1: Radiografie toracică incidență anteroposterioară
(opacitate de intensitate subcostală, relativ bine delimitată
ce ocupă jumătatea superioara a hemitoracelui drept)

---

[*] SPITALUL CLINIC DE URGENTA MILITAR CENTRAL DR. CAROL DAVILA – Secția Clinică de Chirurgie Toracică

Examenul computer tomograf toracic decelează masa cu structura tisulară, neomogenă, cu dimensiuni de 21/18/16 cm, localizată la nivelul lobului superior drept şi inferior drept; adenopatii de 2,7cm diametrul axial şi bloc adenopatic voluminos de aproximativ 6/3,8 cm cu zona de necroza centrală, localizate paratraheal drept.(fig.2, fig.3)

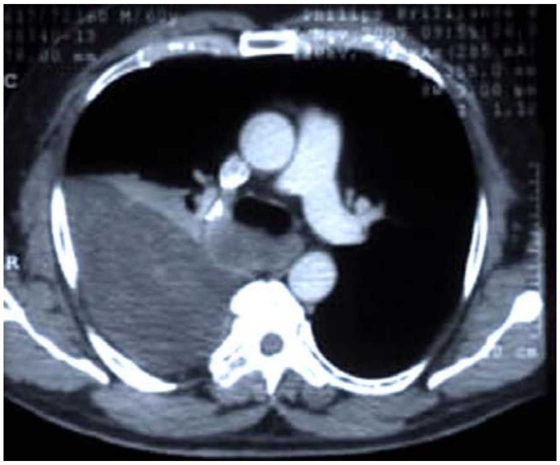

Fig. 2 Examen CT toracic
(tumora solidă localizată la nivelul lobului superior şi inferior drept; bloc adenopatic paratraheal şi retrotraheal drept)

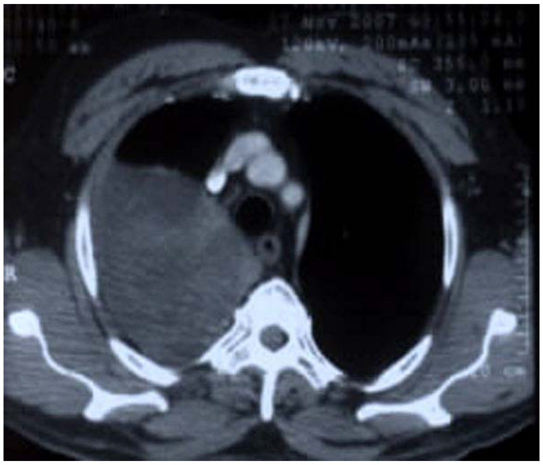

Fig. 3 Examen CT toracic
(tumora solidă localizată la nivelul lobului superior drept, în contact cu traheea)

Traheofibrobronhoscopia descrie: pintene la bronşia lobară superioară dreapta rotunjit cu obstrucţie prin compresiune extrinseca anterioară şi posterioară, cu edem zonal şi obstrucţie cvasicompletă la bronşia segmentară apicală a lobului superior drept.

S-a intervenit chirurgical prin toracotomie anterolaterală dreapta prin spaţiul 4 intercostal, intraoperator decelându-se(fig.4, fig.5) formaţiune tumorală solida, ovoida, albicioasa, voluminoasa, situată la nivelul mediastinului visceral şi posterior, ce comprimă parenchimul pulmonar al lobului superior drept şi inferior drept, comprimă traheea lateral drept şi posterior şi esofagul toracic superior faţă de care pare să nu aibă plan de clivaj.

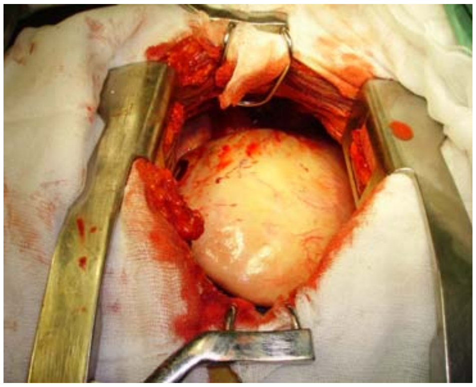

Fig.4 Aspect intraoperator
(tumora dezvoltată în cavitatea pleurala dreapta)

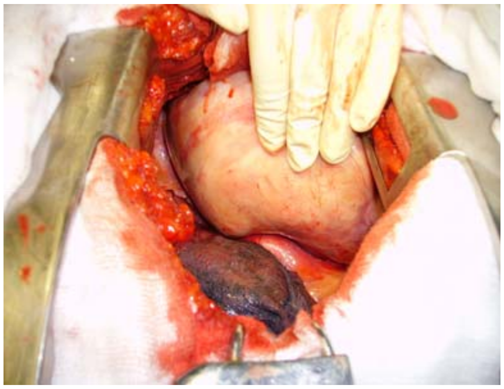

Fig.5 Aspect intraoperator
(tumora comprima parenchimul pulmonar pe care nu îl invadează)

Mobilizarea formațiunii tumorale decelează apartenența de nervul vag drept. Se constată că formațiunea tumorală prezintă două porțiuni(in iceberg): o porțiune de 6/5/3 cm. dezvoltată în mediastinul posterior în contact intim cu esofagul şi nervul vag drept din care formațiunea tumorală se dezvolta şi o a doua porțiune de dimensiuni mult mai mari, dezvoltată în mediastinul visceral şi cavitatea pleurală dreaptă pe care o ocupă în jumătatea ei superioară.

Cele două porțiuni sunt limitate de crosa venei azygos (fig.6). Se rezecă crosa venei azygos(fig.6), după care se procedează la extirparea formațiunii tumorale dezvoltată în cavitatea pleurală dreapta(fig.8), abandonându-se porțiunea dezvoltata în mediastinul posterior.

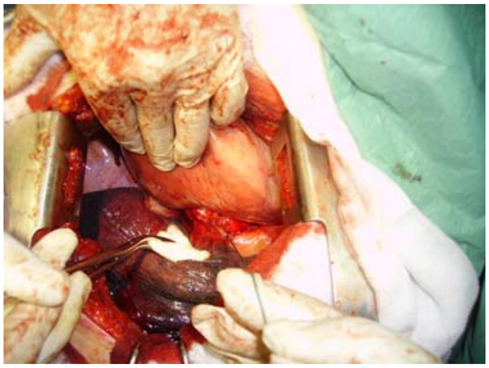

Fig.6 Aspect intraoperator
(rezecția crosei venei azygos)

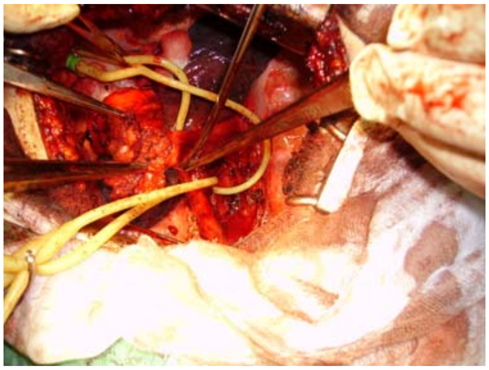

Fig.7 Aspect intraoperator
(rezecția nervului vag drept)

Se procedează la disecția formațiunii din mediastin fata de coloana vertebrala şi de trahee. Se confirmă originea din nervul vag drept(fig.7) care este rezecat. Disecția față de esofag se face în planul submucos esofagian, practicându-se esomiomectomie extramucoasă. Se practică astfel excizia în totalitate a formațiunii tumorale.(fig.9). Examen extemporaneu: tumora neurogena benigna.

(porțiunea tumorală dezvoltată în
cavitatea pleurală dreapta)

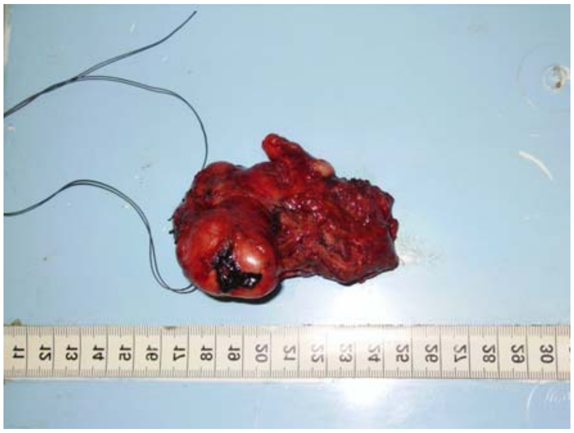

Fig.9 Piesa de rezecție 2
(porțiunea tumorală dezvoltată în
mediastinul posterior)

Evoluție postoperatorie favorabilă cu expansionare completă a parenchimului pulmonar(fig.10).

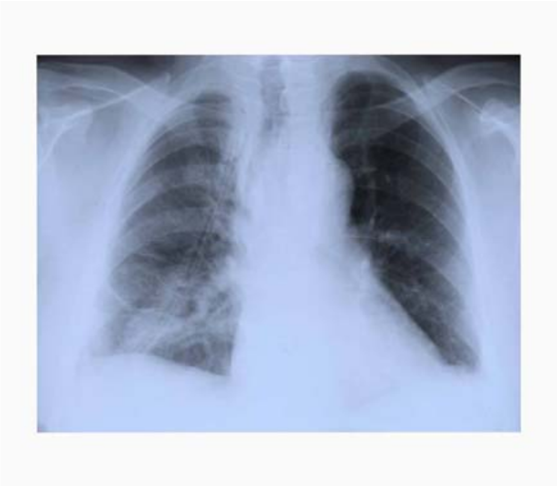

Fig. 10 Radiografie postoperatorie (expansionare completă a parenchimului pulmonar)

Examen histopatologic la parafina: neurofibrom

DISCUTII

Tumorile neurogene mediastinale îşi au originea în celulele ce derivă din creasta neurală, celulele din care se dezvoltă sistemul nervos periferic. Aceste celule cu origine ectodermala sunt: celule ganglionare din ganglionii spinali şi din sistemul nervos autonom, celule paraganglionare din sistemul simpatic şi parasimpatic, celule Schwann şi celule satelite. Țesutul conjunctiv de susținere, de origine mezodermala participă la formarea acestor tumori. Schwanoamele, neurofibroamele şi schwanomul malign se dezvoltă din nervii periferici, iar ganglioneuromul, ganglioneuroblastomul, neuroblastomul se dezvoltă din ganglionii nervoşi simpatici.

Copiii şi adulții tineri sunt mult mai susceptibili de a dezvolta tumori cu originea în ganglionii nervoşi autonomi, două treimi din aceste tumori având caracter malign. La adulți majoritatea tumorilor neurogene se dezvoltă din nervii periferici, 98% din acestea fiind benigne. Neurofibroamele reprezintă aproximativ 25% din tumorile neurogene mediastinale dezvoltate din nervii periferici. Neurofibroamele dezvoltate la nivelul nervului vag intratoracic sunt extrem de rare(cca. 1%).

Gayola şi colaboratorii au strâns din literatura de specialitate 20 de cazuri de neurofibroame dezvoltate din porțiunea intratoracică a nervului vag.

Neurofibroamele apar ca tumori boselate ce par a fi încapsulate, dar fără a avea o capsulă adevărată din țesut conjunctiv. Microscopic se descrie o proliferare de celule schwann şi de celule perineurale în proporție egală. Microscopia electronica evidențiază celule alungite, axoni mielinizați şi nemielinizați, stroma colagenică extensivă.

O proporție de 30-45% din pacienții cu neurofibrom mediastinal au boala Recklinghausen. Neurofibroamele multiple sau neurofibromul plexiform sunt patognomonice pentru neurofibromatoza. Riscul degenerării maligne a neurofibroamelor la această categorie de pacienți este crescut până la 10%.

Tumorile neurogene dezvoltate din porțiunea intratoracică a nervului vag sunt de cele mai multe ori asimptomatice şi sunt descoperite cu ocazia efectuării unei radiografii toracice. Simptomatologia este dată de compresiunea structurilor anatomice învecinate şi este reprezentată de tuse, disfonie, dispnee, dureri toracice. Simptomatologia ce ar putea fi atribuită interesării tumorale a fibrelor vagale destinate inervării cordului, musculaturii bronşice sau gastrointestinale nu a fost descrisă în practica şi în literatura de specialitate.

Examenul radiologic şi examenul computer tomograf pun în evidență formațiunea tumorală, apreciază caracterele tumorii şi relația cu structurile anatomice învecinate.

Examenul RMN poate aprecia etiologia tumorii neurogene: în neurofibroame fiind caracteristic un semnal de intensitate înalta în periferie şi de intensitate medie în centru în modul T2.

Excizia tumorală este recomandată nu doar pentru a confirma natura leziunii ci şi pentru a preveni continuarea evoluției şi compresia structurilor mediastinale învecinate. Pentru tumorile benigne, intervenția chirurgicală este curativă.

CONCLUZII

Tumorile mediastinale neurogene, considerate a fi cele mai frecvente tumori mediastinale, au fost devansate în ultimii ani de către timoame şi limfoame.

Dintre tumorile mediastinale neurogene, tumorile dezvoltate din nervul vag sunt extrem de rare, dar ele trebuie luate în considerație în diagnosticul diferențial al formațiunilor tumorale mediastinale.

Am considerat utila prezentarea acestui caz datorită rarității, volumului tumoral, cât şi al problemelor de tactică operatorie pentru excizia completă a formațiunii.

Incompetența sfincterului uretral

Dr. O. NICODIN[*], dr. B. PANAITE,
dr. N. NICULESCU, dr. Mariana ŞERBAN,
dr. Mirela Vasile, dr. Anca MURARIU

DEFINIȚII

Când o femeie tuşeşte şi pierde urină este vorba de incontinență la stres, termen inventat de Sir Eardley Holland în 1928. Cercetările au arătat că multe afecțiuni pot duce la incontinență la stres şi de aceea aste bine să folosim acest termen doar pentru simptome şi semne. În 1976, ICS a adoptat termenul „ incontinență reală la stres" (GSI) care a fost definit ca pierderea involuntară de urină prin uretră când presiunea intravezicală depăşeşte presiunea uretrală maximă în absența activității detrusorului (Abrams şi colaboratorii 1988). Se preferă termenul „incompetența sfincterului uretral" (USI) care indică mai exact fiziopatologia.

Folosim în continuare simptomul de „pierdere involuntară de urină la efort fizic" şi semnul de observare a pierderii de urină prin uretră în timpul activităților fizice.

Definitions:

When a woman coughs and loses urine, it means the stress insufficiency, a word invented by Sir Eardley Holland in 1928. The scientific research has indicated that many diseases can lead to stress insufficiency, and that is why it is good to use this word just for symptoms and signs. In 1976, ICS has adopted the notion "real stress insufficiency" (GSI) which was defined as the involuntary loss of urine by urethra when the intra-vesicle pressure passes beyond the highest urethral one in the lack of activity of the detrussor muscle (Abrams & co-workers, 1988). They would rather have the notion "urethral sphincter insufficiency" (USI) which indicates the physiopathology more accurately.

Further on we use the "involuntary loss of urine while physical effort" symptom and the sign of observation of the loss of urine by urethra during sports (physical activities).

ETIOLOGIE

Incompetența sfincterului uretral (ISD) are două cauze – coborârea gâtului vezicii şi a uretrei proximale, şi slăbirea rezistenței uretrale. În mod frecvent cele două cauze apar împreună. La cea dintâi avem de-a face cu o transmitere inegală a presiunii intraabdominale către uretra proximală, ceea ce duce la inversarea gradientului normal de presiune dintre vezică şi uretră, rezultând într-o închidere uretrală negativă.

Când este vorba de scăderea rezistenței uretrale, presiunea intrauretrală în repaus este mai mică decât presiunea intravezicală.

---

[*] Spitalul Clinic de Urgență Militar Central – Secția Ginecologie

Definiția uretrei de joasă presiune este: presiunea uretrală maximă este mai mică de 20 centimetri coloană de apă (Sand şi colaboratorii 2007au presiunea Valsalva în punctul de scurgere este sub 60 centimetri coloană de apă (McGuire şi colaboratorii 1993). Factorii care provoacă aceste stări sunt prezentați mai jos.

Slăbiciunea congenitală a gâtului vezicii e.g. epispadiadis

Ureta şi gâtul vezicii au formă imperfectă din cauza migrării defectuoase şi a fuzionării mezodermului pe linia mediană, ceea ce duce la un gât al vezicii mai lat, o uretră mai scurtă şi deficiențe ale muşchilor netezi şi striați. Simfiza şi clitorisul sunt despicate. Acest fel de incontinență nu poate fi eficient rezolvată prin procedurile convenționale de ridicare a gâtului vezicii, şi se corectează prin creşterea rezistenței uretrale, adică prin folosirea unui sfincter urinar artificial sau a unui agent de umflare a uretrei, e.g. colagenul.

Slăbirea congenitală datorată suportului slab al planşeului pelvian, poate duce la instalarea incontinenței de stres chiar din adolescență, şi aşa se explică procentul de 5-10% de fete cu incontinență (Nemir şi Middleton 1954; Thomas şi colaboratorii 1980). La femeile nulipare, care prezintă incompetența sfincterului uretral s-a observat o deficiență a formării de colagen care duce la reducerea colagenului total şi la scăderea colagenului de tip I (Keane şi colaboratorii 1992).

Provocarea mecanică

Presiunea intra-abdominală crescută, care se întâlneşte la femeile obeze şi la cele cu boli respiratorii cronice, poate duce la incontinență la stres. Obezitatea apare mai mult la femei nulipare aflate în premenopauză şi care prezintă incontinență la stres, decât la femeile pare şi care prezintă incontinență la stres (Creighton şi colaboratorii 1992). Obezitatea poate de asemenea să predispună la incontinență la stres femeile cu slăbiciune congenitală sau de dezvoltare a sfincterului uretral.

Naşterea

Mai multe naşteri pe cale vaginală cresc riscul de incontinență la stres (Foldspang şi colaboratorii 1992; Wilson şi colaboratorii 1996).

Chaliha şi colaboratorii (1999) au descoperit într-un studiu prospectiv efectuat pe 549 de femei nulipare că prevalența incontinenței la stres înainte, în timpul şi după naştere a fost de respectiv 3,6%, 43,7% şi 14,6%. Într-un studiu ulterior efectuat pe 286 de femei nulipare, care a urmărit investigarea urodinamică în al treilea trimestru, s-a observat o prevalență a incontinenței reale la stres de 9,1% şi 5% la cele 161 de femei care au revenit la 12 săptămâni după naştere (Charliha şi colaboratorii 1998). La acest grup de femei simptomele post-partum de incontinență la stres au fost asociate celui de-al doilea stadiu de travaliu activ de mai mare durată. Naşterea poate duce la incontinență la stres ca urmare a denervării componentelor netede şi striate ale mecanismului sfincterului, planşeului pelvian şi fasciilor pubocervicale (Snooks şi colaboratorii 1984; Sayer şi colaboratorii 1989) sau ca urmare a schimbărilor apărute în mecanismul de susținere a uretrei (Peschers şi colaboratorii 1996).

Menopauza

Deficitul de estrogen poate provoca slăbirea suportului gâtului vezicii şi pierderea închiderii ermetice a uroteliului. Cu toate acestea, studiile privind folosirea estrogenului nu au dovedit nici o îmbunătățire semnificativă a incontinenței la stres (Fantl şi colaboratorii 1994).

Traumatismul

Aceste implică fractura inelului pelvian şi diastaza simfizei cu desprinderea gâtului vezicii de ligamentele pubouretrale care îl leagă de spatele simfizei (Stanton şi colaboratorii 1981).

Operații în antecedente

Operațiile efectuate în apropierea gâtului vezicii pentru corectarea prolapsului sau a incompetenței sfincterului uretral pot duce la recidive ale incontinenței. Mecanismul nu este bine elucidat dar poate include afectarea sfincterului uretral, scăderea rezistenței uretrei sau a presiunii de închidere, fibroza post-operatorie ce afectează uretra şi țesutul parauretral, fixarea uretrei de spatele simfizei cu pierderea elasticității, şi eşecul de ridicare a joncțiunii uretrovezicale. În urma unui studiu efectuat pe 120 de femei cu incontinență reală la stres dovedită urodinamic, Hilton Stanton (1983) au descoperit că operațiile repetat nereuşite erau asociate cu presiunea uretrală scăzută.

Medicamente

Medicamentele hipotensive cum ar fi prazosin, reserpine, alpha-methyldopa şi phenoxybenzamine acționează prin inhibarea receptorilor $\alpha - 1 -$ adrenergici, şi duc la incontinență urinară (Kiruluta şi Andrews 1983; Dwyer şi Teele 1992).

Muşchi netezi ai uretrei proxime şi ai gâtului vezicii sunt inervați simpatic (Awad şi colaboratorii 1976) şi blocajul $\alpha -$ adrenergic are un efect relaxant prin scăderea presiunii uretrale (Anderson şi colaboratorii 1981).

Simptome

Simptomul clasic al incompetenței sfincterului uretral este incontinența la stres; totuşi, multe paciente acuză frecvența, incontinența de urgență şi incontinența la poziția stând în picioare (Cardozo şi Stanton 1980). În general incontinența la stres se agravează în săptămâna ce precede ciclul menstrual. Întreruperea jetului poate fi confirmată obiectiv la aproximativ 83% din pacientele cu incompetență a sfincterului şi la 87% din pacientele cu instabilitate a detrusorului, astfel încât acest simptom nu ne poate ajuta să diferențiem cele două tulburări. Pacientele sunt cel mai adesea multipare. Simptomele apar de obicei în timpul sarcinii şi se agravează în perioada postnatală şi în următoarele sarcini (Stanton şi colaboratorii 1980; Chalila 1999).

Semne

La examenul clinic nu apar trăsături speciale generale sau neurologice. Epispadis este uşor de recunoscut. Coborârea peretelui vaginal anterior (cistouretrocel) este prezentă la aproximativ 50% din femeile cu incompetența sfincterului. Trebuie evaluate capacitatea şi mobilitatea vaginului (care indică afectarea vaginului) deoarece acestea pot fi relevante în stabilirea variantei chirurgicale pentru redobândirea continenței. Trebuie notate şi alte probleme de prolaps genital sau de patologie uterină sau ovariană ca să se poată efectua chirurgia reparatorie şi pentru aceste elemente odată cu cea pentru continență.

Investigații

Vezica nu oferă dovezi sigure. Mulți clinicieni au demonstrat discrepanțe între rezultatele clinice şi cele urodinamice (Haylen şi Frazer 1987; Ng şi Murray 1989). Dificultatea constă în complexitatea acuzelor. O combinație a incontinenței la stres, incontinenței de urgență şi frecvenței sugerează foarte probabil instabilitatea detrusorului. În urma unui studiu urodinamic efectuat pe un număr de 800 de femei, aproximativ 50% au fost diagnosticate cu incompetența sfincterului uretral.

Din acestea doar 31% aveau simptomul şi semnul de incontinență la stres, iar 1,5% prezentau doar simptomul de incontinență la stres (Haylen şi Frazer 1987). Din tot grupul 85% prezentau iminență, incontinență la iminență şi la stres dar numai 25% au dovedit la testare instabilitatea detrusorului.

La fel s-a întâmplat şi cu tulburările de golire: 53% prezentau două simptome ale tulburărilor de golire care au fost confirmate doar în 10% din cazuri prin testare.

Scopurile testelor urodinamice sunt:

1. Să confirme simptomele (e.g. incontinenţa sau dificultatea la golire) şi gravitatea lor
2. Să ducă la stabilirea diagnosticului
3. Să depisteze alte anomalii, e.g. instabilitatea detrusorului
4. Să confirme modalitatea de rezolvare

Testele urodinamice trebuie precedate de efectuarea unei mostre negative de jet de urină pentru a evita procedurile invazive care ar agrava infecţia de la nivelul tractului urinar, deoarece altfel rezultatele ar fi neconcludente.

Cistometria şi videouretrografia

Diagnosticul cistometric de scurgere urinară indică prezenţa instabilităţii detrusorului sau a dificultăţilor de golire; doar dacă nu apare instabilitatea detrusorului se poate ajunge prin excludere la diagnosticul de incompetenţă a sfincterului uretral. Combinaţia cistometriei şi screeningului rediologic cu inregistrarea video, împreună cu comentariul ecografic, permite stabilirea altor diagnostice, inclusiv a cauzei incontinenţei la poziţia de stat în picioare, şi a prezenţei unui diverticul uretral, şi uneori prezenţa fistulelor urinare). Altfel contribuie prea puţin la stabilirea clară a incompetenţei sfincterului uretral (Stanton şi colaboratorii 1986).

Profilometria presiunii uretrale

Rolul profilometriei presiunii uretrale (UPP) în diagnosticarea incompetenţei sfincterului uretral rămâne controversat. Versi şi colaboratorii (1986) au declarat că „suprapunerea între normal şi GSI (USI) a fost atât de mare încât a făcut imposibilă diagnosticarea corectă". Sand şi colaboratorii (1987) au măsurat presiunea de închidere uretrală şi au stabilit că o scădere de 20 centimetri coloană de apă indică o uretră cu presiune scăzută, şi reprezintă un element important în eşecul chirurgiei reparatorii.

Hilton (1988) a cercetat conceptul de uretră instabilă ca şi cauză a incompetenţei sfincterului şi a descoperit că o schimbare relativă de 30% a presiunii maxime de închidere uretrală era elementul cel mai sigur în detectarea acestei afecţiuni. Principalul dezavantaj al presiunii uretrale este relativa instabilitate a cateterului, care duce la rezultate false sau suprapuse la pacientele continente şi incontinente.

Presiunile Valsalva în punctul de scurgere (VLPP)

Această tehnică de diagnosticare relativ recentă poate fi folosită pentru a măsura rezistenţa uretrală în diagnosticarea deficienţei intrinseci a sfincterului. O presiune de sub 60 de centimetri coloană de apă în poziţie stând în picioare la un volum de 150 ml dovedeşte deficienţa intrinsecă a sfincterului.

Testul este considerat foarte exact şi cu mare procent de repetare la aproximativ 80% din pacientele adulte cu USI (Bump şi colaboratorii 1995). În comparaţie cu UPP, VLPP dă rezultate similare dar testul este mai puţin costisitor şi durează mai puţin (Theofrastous şi colaboratorii 1995). Totuşi, Alcalay şi colaboratorii (1994) au găsit o specificitate crescută (100%) dar o sensibilitate redusă (69%) în diagnosticarea incontinenţei reale la stres, şi precizie redusă în diagnosticarea incontinenţei la stres în comparaţie cu variabilele UPP.

Ecografia

Ecografia depistează golirea incompletă a vezicii care poate duce la incontinenţă la stres. Poate permite evaluarea poziţiei şi deplasării gâtului vezicii, relevante în diagnosticarea incompetenţei sfincterului uretral şi poate fi utilă în analizarea eşecului chirurgiei convenţionale şi în alegerea finală a altei operaţii (Creighton şi colaboratorii 1994).

Concluzii

Multitudinea de proceduri de diagnosticare existente pentru evaluarea pacientelor cu simptome în zona tractului urinar inferior că unul sau două teste nu pot oferi informații decisive. În general, medicii trebuie să treacă de la testele mai simple la cele mai complexe numai dacă diagnosticarea corectă nu se poate realiza prin testele simple.

Testele cele mai eficiente din punctul de vedere al costului şi timpului şi care oferă cea mai concentrată informație, indicând direcția unei testări ulterioare sunt testul de tuse, cistometria pe un canal, Q tip test, şi reziduul după golire. După eliminarea posibilității de infecție şi după examinarea fizică şi anamnezică minuțioasă, aceste teste simple sunt obligatorii.

Toate testele trebuie reținute şi analizate cu grijă. Numai un clinician perspicace poate sintetiza aceste date şi poate decide un diagnostic corect şi un tratament rațional.

SISTEMUL DE SERVICII DE ASISTENȚĂ SOCIO-MEDICALĂ ŞI ÎNGRIJIREA PERSOANELOR DE VÂRSTA A TREIA

Drd. ing**. Vasilica STRICHEA**[*]

Scopul protecției sociale este de a asigura, un trai decent categoriilor de persoane aflate în dificultate, permițându-lc în acelaşi timp să accepte şi să se adaple/e evyluțiiloF economice şi sociale.

Obiectivul sistemului de protecție socială constă în susținerea persoanelor aflate în dificultate care nu pot prin resurse proprii să ducă o viață normală.

Protecția socială este alcăluiul din diverse *beneficii sociale* (în natură sau în bani) care suplinesc un delicii de resurse ale persoanei, grupurilor şi colectivităților aflate în dificultate şi *servicii sociale* care se adresează unui *deficit de capacități* ale individului de a face față problemelor vieții.

Asistența socială asigură prin serviciile specializate punerea în aplicare a programelor şi măsurilor de protecție socială în vederea depăşirii perioadelor de criză şi refacerea forțelor proprii a personelor aflate în dificultate pentru a se integra în viața socială.

protecție socială **servicii sociale** **asistență socială**

În aplicarea măsurilor de protecție socială, statul român a urmărit respectarea prevederilor Constituției României referitoare la drepturile omului, precum şi o serie de principii, printre care se menționează: *protecția demnității umane, universalitatea măsurilor de protecție socială, promovarea principiilor solidarității şi justiției sociale, promovarea parteneriatului social ca mijloc central şi de eficientizare a tuturor măsurilor de politică şi protecție socială, trecerea treptată de la descentralizarea realizării protecției sociale şi, odată cu aceasta, angajarea în activitatea de protecție socială a agenților economici, a unităților adminstrației publice locale, a instituțiilor guvernamentale şi neguvernamentale, a societăților de caritate şi a persoanelor fizice prin contribuții materiale, băneşti şi sociale ale acestora într-un cadru legal adecvat.*

Scopul protecției sociale este de a asigura un trai decent categoriilor de persoane aflate în dificultate, permițându-le în acelaşi timp să accepte şi să se adapteze evoluțiilor economice şi sociale.

Obiectivul sistemului de protecție socială constă în susținerea persoanelor aflate în dificultate care nu pot prin resurse proprii să ducă o viață normală.

Protecția socială este alcătuită din diverse *beneficii sociale* (în natură sau în bani) care suplinesc un deficit de resurse ale persoanei, grupurilor şi colectivităților aflate în dificultate şi *servicii sociale* care se adresează unui *deficit de capacități* ale individului de a face față problemelor vieții.

Beneficiile sociale sunt şi ele la rândul lor de mai multe feluri:

- Beneficii sociale contributorii - se mai numesc şi *beneficiile de asigurări sociale* şi se acordă cu condiția plății contribuției la fondul de asigurări socialale – pensiile, ajutorul de şomaj, ajutorul de boală.

---

[*] Direcția Medicală – Secția medicală şi relații internaționale

- Beneficile sociale non-contributorii – se mai numesc şi *beneficii de asistență socială* deoarece ele completează deficitul de resurse ale persoanelor aflate în dificultate, fără a plăti, în prealabil, o contribuție, iar acestea constau în alocațiile pentru copii, bursele de studii, gratuități sau reduceri la transport, subvenții pentru chirii, etc.

Serviciile sociale cuprind serviciile oferite de colectivitate, în mare măsură, în afara sistemului economic şi se împart în trei categorii: învățământ, sănătate şi asistență socială. Învătământul asigură dezvoltarea capacităților intelectuale şi tehnice al individului, sănătatea asigură prevenția şi integritatea capacităților fizice ale persoanei şi recuperarea acestora în caz de boală, serviciile de asistență socială sprijină persoanele aflate în dificultate şi pe cele care se confruntă cu probleme dificile de viață, susțin refacerea abilităților deteriorate şi încearcă reintegrarea socială a acestora.

Serviciile de asistență socială se acordă fie în *mediul natural de viață al individului sau colectivității*, de exemplu: acasă, la locul de muncă, fie în *instituții de asistență socială* – centre pentru copiii străzii, case pentru vârstnici, instituții pentru persoane cu dizabilități, etc.

Obiectivul central al asistenței sociale este de a sprijini prin diferite mijloace persoanele, grupurile şi comunitățile aflate în dificultate, care nu pot depăşi prin resurse proprii această situație, datorită unor cauze de natură economică, biologică sau psihologică, culturală, acordându-le ajutorul pentru a duce o viață decentă.

Categoriile de persoane beneficiare ale asistenței sociale sunt: copiii abandonați şi instituționalizați; persoanele vârstnice neajutorate, abandonate şi instituționalizate; persoanele dependente de droguri, de alcool; tinerii neintegrați social; familiile sărace; persoanele abuzate fizic, sexual; persoanele cu handicap fizic sau mintal; persoanele cu boli cronice fără susținători legali; persoanele care au suferit din cauza calamităților de orice fel.

Asistența socială asigură prin serviciile specializate punerea în aplicare a programelor şi măsurilor de protecție socială în vederea depăşirii perioadelor de criză şi refacerea forțelor proprii a personelor aflate în dificultate pentru a se integra în viața socială.

Serviciile sociale, în conformitate cu prevederile art.1 alin. 1 din Ordonanța Guvernului nr. 68/2003, *reprezintă ansamblul complex de măsuri şi acțiuni realizate pentru a răspunde nevoilor sociale individuale, familiale sau de grup,în vederea prevenirii şi depăşirii unor situații de dificultate, vulnerabilitate sau dependenta pentru prezervarea autonomiei şi protecției persoanei, pentru prevenirea marginalizării şi excluziunii sociale, pentru promovarea incluziunii sociale şi în scopul creşterii calității vițtii.*

Clasificarea serviciilor sociale

Serviciile sociale se organizează la nivel comunitar şi pot fi :

- servicii de asistență socială
- servicii de îngrijire social-medicale

Serviciile de asistență socială se clasifică în ***servicii sociale primare şi servicii sociale specializate*:**

➢ *Serviciile sociale primare* au un caracter general si urmaresc prevenirea sau limitarea unor situatii de dificultate sau vulnerabilitate. Principalele activitati desfasurate in cadrul serviciilor sociale primare sunt:

a) activități de identificare a categoriilor de persoane cu nevoi sociale;

b) activitati de depistare a situațiilor de risc şi de informare despre drepturile şi obligațiile persoanei beneficiare de servici sociale;

c) luarea de măsuri în vederea reducerii efectelor situațiilor de criză a persoanelor aflate în situații de risc;

d) măsuri şi acțiuni de sprijin pentru menținerea în comunitate a persoanelor în dificultate;

e) măsuri educative şi activităţi de consiliere a categoriilor de persoane beneficiare de servicii sociale;

f) alte măsuri şi acţiuni de protecţie socială care au drept scop prevenirea sau limitarea unor situaţii de dificultate ori vulnerabilitate, care pot duce la marginalizare sau excluziune sociala.

➢ *Serviciile sociale specializate* au ca scop menţinerea, refacerea şi dezvoltarea capacităţii de funcţionare socială a indivizilor şi familiilor. Activităţile specifice acestor servicii sunt cele de:

a) recuperare, reabilitare şi reinserţie socială a persoanelor aflate în situaţii de risc;
b) suport şi asistenţă pentru familiile şi copiii aflaţi în dificultate;
c) suport şi asistenţă pentru asigurarea unei vieţi autonome şi active persoanelor de vârsta a treia;
d) suport şi servicii de îngrijire acordate vârstnicilor aflaţi într-o situaţie de dependenţă;
e) sprijin pentru inserţia socială şi profesională a persoanelor sau familiilor în dificultate ori în situaţii de risc;
f) sprijin pentru integrarea, readaptarea şi reeducarea profesională, stabilite prin legislaţia în vigoare;
g) acţiuni de informare, susţinere şi consiliere, expertiză ori coordonare în vederea prevenirii oricărei forme de dependenţă;
h) acordarea de sprijin în primirea şi îngrijirea cazurilor de urgenţă, cu sau fără găzduire, a persoanelor sau familiilor în dificultate ori în situaţii de risc;
i) mediere socială;
j) alte măsuri şi acţiuni care au drept scop menţinerea, refacerea sau dezvoltarea capacităţilor individuale pentru depăşirea unei situaţii de nevoie socială.

Serviciile de îngrijire social-medicală se acordă în cadrul unui sistem social şi medical integrat şi au drept scop principal menţinerea autonomiei persoanei, precum şi prevenirea agravării situaţiei de dependenţă. Aceste servicii se acordă şi persoanelor care se găsesc în imposibilitatea de a realiza singure activităţile curente datorită unor afecţiuni fizice, psihice, mentale sau senzoriale sau care se află în faza terminală a unei boli incurabile.

Serviciile de îngrijire social-medicală pot fi de natură socială, medicală şi conexe, astfel:

I. serviciile de îngrijire social-medicală *de natura socială* pot fi următoarele:

a) servicii de bază: ajutor pentru igienă corporală, îmbrăcare şi dezbrăcare, igiena eliminărilor, hrănire şi hidratare, transfer şi mobilizare, deplasare în interior, comunicare;

b) servicii de suport: ajutor pentru prepararea hranei sau livrarea acesteia, efectuarea de cumpărături, activităţi de menaj, însoţirea în mijloacele de transport, facilitarea deplasării în exterior, companie, activităţi de administrare şi gestionare, activităţi de petrecere a timpului liber;

c) servicii de reabilitare şi adaptare a ambientului: mici amenajări, reparaţii.

II. serviciile de ingrijire social-medicală *de natură medicală* sunt reprezentate de activităţi complexe de diagnostic, tratament şi îngrijiri recomandate şi realizate în conformitate cu tipurile de afecţiuni pe care le prezintă beneficiarii acestor categorii de servicii sociale.

III. serviciile de îngrijire social-medicală *de natura serviciilor conexe*, sunt reprezentate de servicii de recuperare şi reabilitare, kinetoterapie, fizioterapie, terapie ocupaţională, psihoterapie, psihopedagogie, logopedie.

O clasificare pe domeniile de intervenţie şi sprijin ale serviciilor sociale poate fi facută din analiza structurii bugetare şi a transferului de competenţe între autorităţile publice. Astfel, în funcţie de adresabilitate, am putea clasifica serviciile sociale ca fiind destinate pentru:

- protecţia persoanelor vârstnice: servicii rezidenţiale, servicii de îngrijire temporară sau permanentă la domiciliu;
- protecţia copilului: centre de zi, centre de plasament, centre de primire în regim de urgenţă, centre maternale, servicii de tip familial;

- protecția familiei: centre de recuperare, centre de prevenire şi centre de informare pentru victimele violenței în familie;
- protecția persoanelor cu dizabilități: centre de îngrijire şi asistență, centre de recuperare şi reabilitare, centre de integrare prin terapie ocupațională;

Etapele procesului de acordare a serviciilor sociale:

- Evaluarea inițială - efectuată de către asistentul social din cadrul serviciului public de asistență socială din subordinea autorităților admininistrației publice locale, cu scop de identificare a nevoilor individuale sau de grup a persoanelor defavorizate social;

- Elaborarea planului de intervenție - cuprinde măsurile necesare soluționării situației de risc social, acordarea de prestații şi servicii sociale precum şi orice alte măsuri sociale;

- Evaluarea complexă – (în cazul în care există situații pentru a căror rezolvare se impune participarea mai multor profesionişti sau instituții specializate) se efectuează pentru identificarea şi stabilirea măsurilor de intervenție personalizate şi are ca scop elaborarea unei strategii de suport continând măsurile şi serviciile adecvate potrivit nevoilor sociale identificate;

- Elaborarea planului individualizat de asistență şi îngrijire cuprinde programarea serviciilor sociale, personalul responsabil precum şi procedurile de acordare; este elaborat de furnizorul de servicii sociale cu acordul şi participarea beneficiarului;

- Monitorizarea prin reevaluarea periodică a situației persoanei beneficiare şi cunoaşterea eficienței serviciilor sociale acordate pentru stabilirea continuării intervenției sau scoaterii din evidență a cazului.

SITUAȚIA ACTUALĂ A SISTEMULUI DE ASISTENȚĂ SOCIALĂ

Analiza profilului actual al sistemului de asistență socială pentru persoanele vârstnice aşa cum este prezentat în *Strategia națională de dezvoltare a sistemului de asistență socială pentru persoanele vârstnice în perioada 2005-2008*

În cazul persoanelor de vârsta a treia se întâlneşte o situație particulară, acestea având nevoie, în egala măsură, de două tipuri de suport :

- **servicii sociale**
- **servicii medicale**.

În aceste condiții, inițierea, dezvoltarea şi acordarea serviciilor sociale şi de sănătate, în special a celor de îngrijire personală, impun o politica unitară în domeniu pentru a realiza menținerea persoanelor vârstnice la domiciliu sau, dacă acest lucru nu este posibil, pentru a asigura suportul necesar continuării vieții într-o instituție de asistență socială.

În prezent, în România, funcționează:

a) 4 cămine pentru persoane vârstnice, cu o capacitate de 2.121 paturi, aflate în coordonarea metodologică a Ministerului Muncii Solidarității Sociale si Familiei;

b) 84 de centre de îngrijire şi asistență pentru adulții cu handicap, cu o capacitate de 10.230 paturi, reprezentând fostele cămine de bătrâni şi cămine spital aflate în coordonarea metodologică a Autorității Naționale pentru Persoanele cu Handicap (39 foste cămine de bătrâni si 45 foste cămine spital care nu şi-au schimbat profilul inițial);

c) 17 instituții de asistență socială (cămine pentru persoane vârstnice şi centre de zi) susținute financiar de organizații neguvernamentale, pentru care se acordă subvenții de la bugetul de stat, cu o capacitate totala de 776 locuri:

d) 39 de servicii la domiciliu subvenţionate de la bugetul de stat. (Sursa: Raportul anual de asistenta sociala al direcţiei de specialitate din cadrul Ministerului Muncii Solidarităţii Sociale si Familiei)

Principalele puncte slabe ale sistemului de asistenta sociala a persoanelor vârstnice:

În raport cu profilul global al sistemului:

- Numărul redus de studii şi cercetări privind tendinţele demografice, particularităţile vârstei a treia şi problematicile specifice vârstnicilor din ţara noastră ;
- Accesul persoanelor vârstnice la îngrijirea în sistem rezidenţial sau la domiciliu, este greoi, el realizându-se în baza mai multor metodologii, prevăzute de legislaţia specială pentru persoane vârstnice şi persoane cu handicap ;
- Dreptul la măsuri de asistenţă socială se acordă pe criterii diferite: evaluarea nevoilor persoanelor vârstnice este realizată de o echipa formată din medic şi asistent social care aplică grila naţională de evaluare a persoanelor vârstnice şi stabileşte gradul de dependenţă; persoana vârstnică cu dizabilităţi este evaluată de Comisia de expertiza a adultului cu handicap care încadrează persoana într-un grad de handicap; *este de subliniat faptul că legislaţia din ţările europene considera persoanele care au dobândit o dizabilitate generatoare de pierdere funcţională la vârsta a treia, drept persoane dependente şi nu persoane cu handicap;*
- Dezvoltare inegală şi inechitabilă a serviciilor sociale destinate persoanelor vârstnice la nivel naţional: exista judeţe cu concentrare masivă de ONG-uri furnizoare de servicii, iar altele în care nu este înregistrată nici o organizaţie activă;
- Absenţa activităţii de monitorizare şi control susţinută de criterii şi standarde clar definite, aplicată de personal calificat în domeniu;
- Servicii de prevenţie şi recuperare insuficiente ;
- Lipsa de colaborare între instituţiile administraţiei centrale şi locale din domeniul asistenţei sociale şi de sănătate, reprezentând principalul obstacol al dezvoltării serviciilor sociale şi medicale integrate, acordate la nivel comunitar;
- Prevederi legale depăşite sau dificil de implementat, cum ar fi: calcularea contribuţiei datorată de persoana vârstnică pentru acordarea serviciilor la domiciliu, facilităţile acordate îngrijitorilor proveniţi din familia beneficiarului, programul de formare mult prea complex faţă de atribuţiile reale ale unui îngrijitor la domiciliu, etc;
- Instituţii de asistenţă socială insuficiente faţă de solicitări, situaţie evidentă în protecţia persoanelor vârstnice, a persoanelor cu boli cronice în mod deosebit a celor cu afecţiuni neuropsihice.
- Incapacitatea sistemului de a rezolva probleme/situaţii personale extrem de grave care nu sunt deloc sau sunt marginal acoperite cu servicii sociale.

În raport cu organizarea:

- Regulamente de organizare şi funcţionale diferite ale instituţiilor care acordă acelaşi tip de servicii, pentru aceleaşi categorii de beneficiari;
- Disproporţie în alocarea de personal în raport cu complexitatea activităţii, precum şi lipsa unor normative de personal elaborate în baza unor evaluări prealabile, cu respectarea standardelor europene în domeniu;
- Existenţa mai multor sisteme de evaluare a deficitului funcţional;
- Sistem managerial informaţional slab dezvoltat, ceea ce conduce la decizii incorecte sau insuficient fundamentate;
- Incapacitatea sistemului de a oferi o imagine comprehensivă asupra numărului de beneficiari şi a serviciilor disponibile;

În raport cu finanțarea:

- Rigiditatea sistemului a generat imposibilitatea direcționării fondurilor în vederea soluționării unor situații de criză;
- Finanțarea instituțiilor de asistență socială din bugetele locale; deşi acestea asigură servicii pentru beneficiari care provin din toate localitățile județului, datorită bugetelor mici aceasta a condus la degradarea multor instituții sub aspect fizic şi funcțional;
- Neaplicarea legislației referitoare la convențiile ce se încheie pentru îngrijirea unei persoane vârstnice într-un cămin situat în alt judeţ, autoritatea locală unde îşi are domiciliul persoana fiind obligată să asigure cheltuielile necesare asistării acesteia;
- Nedefinirea clară a modalităților de finanțare a serviciilor sociale, astfel încât să fie asigurată sustenabililatea şi continuitatea acestora;

În raport cu resursele umane:

- Sub-dimensionarea necesarului de personal la nivel central şi local;
- Lipsa personalului calificat la nivelul serviciilor publice de asistență socială, dar şi la nivelul serviciilor şi instituțiilor de asistență socială destinate asistării persoanelor vârstnice;
- Reglementări insuficiente referitoare la nevoia de formare şi criteriile de acreditare a personalului care activează în domeniul serviciilor sociale pentru persoane vârstnice, respectiv lipsa standardelor profesionale care să permită atât includerea în Clasamentul Ocupațiilor din România, cât şi o salarizare corespunzătoare;
- Titulaturi diferite utilizate pentru personalul care are atribuții similare (asistent personal, îngrijitor la domiciliu);
- Insuficienta dezvoltare a sistemului de formare continuă în vederea dezvoltării de competențe;
- Lipsa unor profesii necesare managementului serviciilor sociale pentru persoane vârstnice: asistentul medical comunitar (echivalent al nursei comunitare), asistentul medical de geriatrie şi gerontopsihiatrie, managerul de caz, terapeutul ocupațional specializat în recuperarea persoanelor vârstnice, etc;
- Deşi cu tradiție în medicina românească, există blocaje în dezvoltarea specialității şi competențelor în geriatrie-gerontologie.

Instituții de asistență socială pentru persoane vârstnice

Definirea termenilor cămin-spital şi unitate medico-socială conform legislației

A. Cămine-spital

Organizarea şi funcționarea căminelor pentru persoane vârstnice:

Asistența socială pentru persoane vârstnice se acordă în conformitate cu prevederile Legii nr. 17/2000, unde se menționează că sunt considerate persoane vârstnice, persoanele care au împlinit vârsta de pensionare stabilită de lege.

- Căminul pentru persoane vârstnice este instituția de asistență socială unde se asigură condiții corespunzătoare de găzduire şi de hrană, îngrijiri medicale, recuperare şi readaptare, activități de ergoterapie şi de petrecere a timpului liber, asistență socială şi psihologică.
- Căminele pentru persoane vârstnice au secții pentru:
  a) persoane dependente;
  b) persoane semidependente;
  c) persoane care nu sunt dependente.
- Cheltuielile curente şi de capital ale căminelor pentru persoane vârstnice se asigură din venituri extrabugetare şi din subvenții sau transferuri acordate de la bugetul de stat.

Principalele obiective:

a) să asigure persoanelor vârstnice îngrijite maximum posibil de autonomie şi siguranţă;

b) să ofere condiţii de îngrijire care să respecte identitatea, integritatea şi demnitatea persoanei vârstnice;

c) să permită menţinerea sau ameliorarea capacităţilor fizice şi intelectuale ale persoanelor vârstnice;

d) să stimuleze participarea persoanelor vârstnice la viaţa socială;

e) să faciliteze şi încurajeze legaturile interumane, inclusiv cu familiile persoanelor vârstnice;

f) să asigure supravegherea şi îngrijirea medicală necesară, potrivit reglementarilor privind asigurările sociale de sănătate;

g) prevină şi să trateze consecinţele legate de procesul de îmbătrânire.

B. Unităţile medico-sociale

Beneficiarii serviciilor acordate în unităţile de asistenţă medico-sociale sunt persoane cu afecţiuni cronice care necesită permanent sau temporar supraveghere, asistare, îngrijire, tratament şi care, din cauza unor motive de natură economică, fizica, psihică sau socială, nu au posibilitatea să îşi asigure nevoile sociale, să îşi dezvolte propriile capacităţi şi competenţe pentru integrare socială.

- Unităţile medico-sociale sunt instituţii publice, specializate, cu personalitate juridică, în subordinea autorităţilor publice locale, care acordă servicii de îngrijire, servicii medicale precum şi servicii sociale persoanelor cu nevoi medico-sociale.
- Unităţile medico-sociale se înfiinţează ca instituţii rezidenţiale sau de zi, prin hotărâre a consiliului local sau judeţean, respectiv a Consiliului General al municipiului Bucureşti, prin reorganizarea unor unităţi sanitare, cu avizul Ministerului Sănătăţii Publice şi al Ministerului Internelor şi Reformei Administrative.
- Înfiinţarea de unităţi medico-sociale permite transferul unor servicii medicale – internări de lungă durată, îngrijiri la domiciliu – din activitatea spitalelor către aceste unităţi, astfel încât spitalele să se poată concentra pe furnizarea îngrijirilor medicale de durată scurtă/medie.
- Bunurile aflate în administrarea unităţilor sanitare care se reorganizează trec în administrarea unităţilor de asistenţă medico-sociale, conform protocolului de predare-primire încheiat între acestea.
- Personalul existent în unităţile sanitare care se reorganizează se preia de către unitatea de asistenţă medico-socială, cu încadrarea în statul de funcţii aprobat.
- Cheltuielile curente şi de capital se asigură din venituri proprii şi din subvenţii acordate din bugetul local, în funcţie de subordonare.
- Conducerea acestui tip de unităţi, este asigurată conform legislaţiei în vigoare, de către un director, sprijinit de un Consiliu Consultativ compus din 5 membri, desemnaţi din partea autorităţii publice locale prin a cărei hotărâre s-a înfiinţat unitatea medico-socială, a direcţiei de sănătate publică, a direcţiei generale de muncă şi solidaritate socială, a casei de asigurări de sănătate judeţene, respectiv a Municipiului Bucureşti şi din partea societăţii civile.
- Personalul unităţilor de asistenţă medico-socială este alcătuit din personalul medical preluat de la unitatea sanitară care s-a transformat. Pregătirea specifică acestui tip de activitate se va realiza prin cursuri de perfecţionare organizate de Ministerul Sănătăţii Publice, în colaborare cu Ministerul Muncii, Solidarităţii Sociale şi Familiei.
- Internarea persoanelor cu nevoi medico-sociale în unităţile cu acest profil se realizează la recomandarea unităţilor sanitare sau la solicitarea persoanelor fizice ori juridice, în baza unei grile de evaluare medico-socială, care constituie un instrument de lucru standardizat, prezentat sub forma unei fişe structurată pe componenta medicală şi componenta socială şi reprezintă instrumentul în baza căruia se realizează internarea în unităţile de asistenţă medico-sociale.

Finanțarea unităților medico-sociale

- Sume decontate de casele de asigurări de sănătate pentru servicii medicale furnizate pe bază de contract, conform Contractului-cadru anual;
- Contribuții personale ale beneficiarilor, după caz;
- Sponsorizări, donații, alte venituri potrivit legii.

Analiza posibilității înființării unor unități medico-sociale/cămine-spital în rețeaua sanitară militară

1. Înființarea unor astfel de unități medico-sociale permite transferul unor servicii medicale – internări de lungă durată, îngrijiri la domiciliu – din activitatea spitalelor militare către aceste unități, astfel încât spitalele militare să se poată concentra pe furnizarea îngrijirilor medicale de durată scurtă/medie şi pe activități specifice medico-militare.
2. Pentru intrarea în funcțiune a acestor unități medico-sociale în armată componenta medicală va fi susținută de Direcția Medicală şi CASAOPSNAJ, prin contractarea de servicii medicale cu aceste unități, iar componenta socială de structuri cu responsabilități în domeniu.
3. **Beneficiarii** serviciilor oferite în unitățile de asistenta medico-sociala sunt persoane cu afecțiuni cronice, care necesită, permanent sau temporar, supraveghere, asistare, îngrijire, tratament şi care au totodată şi *dependență socială*. Pentru unitățile medico-sociale ale M.Ap. beneficiari vor fi pensionarii militari şi membrii de familie ai acestora, veteranii şi văduvele de război, persoane care prezintă afecțiuni medicale cronice şi necesită perioade lungi de spitalizare, dar şi ca o formă de protecție socială pentru persoanele vârstnice şi singure.
4. **Internarea** persoanelor cu nevoi medico-sociale în unitățile cu acest profil se realizează la recomandarea unităților sanitare militare sau la solicitarea persoanelor fizice ori juridice, în baza unei grile de evaluare medico-socială, care constituie un instrument de lucru standardizat, prezentat sub forma unei fişe structurată pe componenta medicală şi componenta socială şi reprezintă instrumentul în baza căruia se realizează internarea în unitățile de asistență medico-sociale.
5. **Finanțarea unităților medico-sociale**: sunt cinci surse de finanțare, astfel:
    a) Fondul unic de asigurări sociale de sănătate sume decontate de casele de asigurări de sănătate, pe baza contractelor încheiate cu acestea, pentru finanțarea cheltuielilor de personal aferente medicilor şi asistenților medicali, precum şi a cheltuielilor cu medicamente şi materiale sanitare;
    b) Contribuții personale ale beneficiarilor sau ale susținătorilor legali ai acestora, aprobate în condițiile legii;
    c) Donații, sponsorizări, alte venituri;
    d) Subvenții şi transferuri de la bugetul de stat ;
    e) Fonduri puse la dispoziție prin bugetul M.Ap. pentru finanțarea cheltuielilor de reparare şi amenajare a clădirilor în care funcționează unitățile medico-sociale.

Pentru prevenirea, limitarea sau înlăturarea efectelor temporare sau permanente ale unor situații care pot genera marginalizarea sau excluderea socială a unor persoane, vrem să ne adresăm unei categorii defavorizate, persoanelor cu probleme sociale şi medicale care se internau în spitalele militare, aceste cazuri putând fi preluate de unitățile medico-sociale înființate în rețeaua sanitară militară.

INSTRUCȚIUNI PENTRU AUTORI

Revista de Medicină Militară este o publicație de prestigiu, cu o vechime de peste 100 de ani. În scopul integrării revistei în circuitul internațional al publicațiilor ştiințifice, autorii sunt rugați să respecte *„Cerințele uniforme pentru manuscrisele trimise jurnalelor biomedicale”* (stilul Vancouver de prezentare) (vezi: New England Journal of Medicine 1991, 324 : 424 – 428; British Medical Journal, 1991, 302; Romanian Jurnal of Gastroenterology 1992, 1/4, 1996, 5/1).

Revista de Medicină Militară este creditată de Colegiul Medicilor din România ca publicație ştiințifică (5 credite pentru abonament), creditarea autorilor făcându-se la solicitarea acestora după prezentarea reprintului obținut ca dovadă a editării lucrării (solicitările vor fi adresate personal de autori Colegiului Medicilor din România – Bulevardul Timişoara nr. 15, sector 6, Bucureşti).

TRIMITEREA MANUSCRISELOR

Manuscrisele vor fi trimise redacției pe adresa: *Revista de Medicină Militară* – Direcția Mediclă, Str.Institutul Medico-Militar Nr. 3-5 sector 1, Bucureşti, tel. 021.319.60.06.

Manuscrisele vor fi însoțite de o scrisoare în care se menționează poziția şi calificarea tuturor autorilor, semnată de toți autorii şi conținând următoarele declarații:

1. Lucrarea este originală, nu a mai fost acceptată pentru publicare, nu este în prezent în considerarea vreunei alte reviste pentru publicare şi nu va fi publicată în altă parte fără permisiunea redacției.

2. În cazul articolelor cu mai mulți autori, trebuie menționat că toți au contribuit în mod direct la programarea, executarea sau analiza lucrării raportate, sau la redactarea acesteia. Autorii sunt rugați să facă aceste declarații cu multă grijă şi responsabilitate. Publicarea precedentă sub formă de rezumat trebuie, de asemenea, menționată.

Studiile pe pacienți umani sau studiile experimentale trebuie să respecte reglementările internaționale de etică. Sursele de finanțare sau suportul financiar trebuie menționat cu mulțumirile de rigoare.

În caz de litigiu este util ca autorii să menționeze numele şi adresa a doi experți pe care îi consideră recomandabili pentru a evalua manuscrisul respectiv.

Lucrările vor fi examinate de către doi revizori de specialitate din comitetul editorial. Dacă opiniile lor diferă, articolul este analizat de un alt revizor. Evaluarea articolelor se face în mod anonim, fără ca revizorii să cunoască numele autorilor lucrării.

Comitetul editorial poate solicita autorilor să modifice manuscrisul, în funcție de recomandările revizorilor. Comitetul editorial are dreptul să editeze (modifice) manuscrisele.

Autorii au întreaga responsabilitate pentru conținutul ştiințific al lucrărilor lor.

Articolele care nu sunt conforme cu stilul revistei, sunt returnate autorilor fără a fi analizate de comitetul editorial.

Timpul de editare va fi cât de scurt posibil, în funcție de necesitățile ştiințifice şi editoriale ale revistei.

Manuscrisele trimise spre publicare nu pot fi returnate. Când se primeşte un manuscris, autorii vor fi informați în scris, într-un interval de cinci-şase săptămâni, cu privire la acceptarea, nevoia de revizuire sau respingerea articolului.

Lucrările publicate vor deveni proprietatea revistei.

După publicare, primul autor va primi zece reprinturi ale articolului, în mod gratuit, pentru a fi distribuite celorlalți autori.

FORMATUL MANUSCRISULUI

Manuscrisul trebuie redactat în conformitate cu *„Cerințele uniforme pentru manuscrisele trimise jurnalelor biomedicale”* (stilul Vancouver de prezentare) (vezi New

England Journal of Medicine 1991, 324 : 424 – 428; British Medical Jurnal of Gastroenterology 1992,1/4, 1996, 5/1).

Articolele se redactează în Microsoft Word, Normal+Justf., Times New Roman, Font Size – 16 Bold pentru titlu, Font Size – 12 pentru text, iar rezumatul Font Size – 10 Bold. Pagina trebuie setată din Page setup la 2cm. marginile, format letter.

Autorii sunt rugaţi să trimită articolul pe dischetă şi două exemplare listate de manuscris (inclusiv pentru tabele şi figuri), rezumatul fiind scris atât în limba română, cât şi în engleză, pe adresa Redacției, tipărite pe o singură faţă a hârtiei A4, la un rând (inclusiv pentru tabele şi referinţe bibliografice), cu margini largi. Pentru textul editat în limba română vă rugăm utilizaţi setarea de limbă („*Romanian”*) pentru tastatură (în „*Control Panel* ”din *Windows*) şi să nu utilizaţi alte tipuri de caractere româneşti. **Nu trimiteţi manuscrisul în limba română fără caracterele specifice româneşti** (diacritice). Toate paginile trebuie numerotate consecutiv, începând cu pagina de titlu, jos pe centrul paginii.

MANUSCRISUL VA FI PREGĂTIT ASTFEL:

1. PAGINĂ DE TITLU

- Titlul lucrării (nu mai mult de 100 de caractere cu spaţii), fără abrevieri;
- Prenumele, iniţiala celui de al doilea prenume, numele de familie al autorilor
- Numele complet al locului de muncă (instituţie şi departament) pentru fiecare autor;
- Adresa de corespondenţă (cu detalii: grade ştiinţifice didactice şi militare, persoana de legătură, telefon, fax, e-mail etc.)

2. PAGINĂ DE REZUMAT

- Rezumatul trebuie să aibă 150, până la 250 de cuvinte şi să cuprindă: obiectivul studiului, material şi metodă, rezultatele fără interpretarea datelor şi concluzii.
- Cuvintele-cheie: 3-4 cuvinte-cheie, după *Index Medicus.*

3. ARTICOLUL PROPRIU-ZIS

a. **Articol original** – cel mult 800-1000 de cuvinte (4 pagini).

b. **Prezentare caz** – cel mult 600-800 de cuvinte (2 pagini)..

c. **Referat general** – cel mult 2.000 de cuvinte (10 pagini).

- **INTRODUCERE**: prezentarea problemei, plasarea în context, scopul şi obiectivele studiului, ipoteza de lucru.
- **MATERIALE ŞI METODE**: pacienţi, procedee, echipament (inclusiv indicaţii cu privire la producător), metoda de lucru, analiză statistică, tehnici operatorii, medicamente etc. (în funcţie de specificul articolului), toate acestea fiind descrise în detalii suficient de amănunţite pentru a permite reproducerea studiului de către alţi investigatori. În tot textul trebuie folosite aceleaşi nume pentru produse (cu specificarea numelui de marcă între paranteze la prima utilizare). Nu se recomandă numele pacienţilor.
- **REZULTATE**: fără interpretări.
- **DISCUŢII**: 1 – analiza rezultatelor prin prisma obiectivelor propuse ale studiului cu comentarii cu privire la aspectele lămurite (pozitive sau negative) sau nelămurite prin acest studiu;

  2 – comparaţie între rezultatele obţinute de autori şi alte studii din literatură, cu explicaţii, eventual ipoteze cu privire la diferenţele observate, accentuând asupra progresului pe care cercetarea de faţă îl aduce;

  3 – comentarii privind importanţa studiului de faţă, precum şi o punere la punct a situaţiei actuale a subiectului investigat atât în literatură, cât şi în practică; eventual se vor prezenta aici cele mai importante studii sau aspecte din domeniu.

4 – probleme nerezolvate, întrebări la care nu s-a răspuns şi care rămân deschise în viitor pentru studiile ce vor urma, eventuale direcţii propuse pentru investigare în domeniul respectiv.

CONCLUZII

La nevoie, aceste capitole mari pot fi împărţite în subcapitole, după necesităţi.

Se recomandă utilizarea precaută a abrevierilor şi menţionarea numelui complet la prima apariţie în

text a abrevierii respective. Toate referinţele bibliografice vor fi citate în text cu cifre arabe, la exponent, fără paranteze, în ordinea apariţiei (de exemplu: Un alt studiu[18] arată...). Toate figurile şi tabelele trebuie să fie citate în text în locul în care ele să apară (exemplu: Fig. 3, Tab. 2). Datele care apar în tabele, legendele tabelelor şi figurilor trebuie să fie rezumate, nu duplicate în text.

4. TABELELE

Tabelele trebuie să fie procesate la două rânduri, pe o pagină separată, numerotate consecutiv (cu referire în text în locul unde ele trebuie să apară) şi cu un titlu (exemplu: **Tabelul 1**. Distribuţia pe vârste şi sex a pacienţilor). Capetele de tabel se scriu cu caractere *italice.* Nu trimiteţi fotografii sau imagini ale tabelelor. Utilizaţi tasta „Tab” pentru a separa coloanele (nu bara de spaţiu) şi utilizaţi tasta „Enter” la terminarea liniei. Toate căsuţele goale din tabel trebuie să aibă o liniuţă. Dacă este nevoie, pentru cuvintele sau frazele lungi din căsuţe se vor utiliza abrevieri, însă cu explicarea acestora în subsolul tabelului. Asiguraţi-vă că toate tabelele sunt citate în text.

5. FIGURILE

Toate figurile (ilustraţiile), fie fotografii, diagrame sau grafice, trebuie să fie de calitate. Ele trebuie să fie numerotate în ordinea apariţiei în text (cu referire în text la numărul figurii în locul în care aceasta ar trebui să apară) şi, să poarte un titlu (exemplu: **Figura 1.** Distribuţia pe vârste şi sexe a pacientelor).

Pe această pagină referitoare la figuri, se va face o listă a tuturor numelor figurilor, în ordine numerică (la nevoie, cu legende explicative; identificaţi, în această legendă, orice literă sau săgeată utilizată pe figură).

Toate figurile trebuie să aibă o etichetă pe spatele lor, care să conţină numele figurii, numele primului autor şi o săgeată care indică marginea de sus a imaginii. Nu scrieţi direct pe dosul fotografiilor. Nu îndoiţi, nu ştergeţi, nu lipiţi, nu prindeţi cu agrafe şi nu mototoliţi ilustraţiile. Fotografiile preparatelor histologice trebuie să aibă menţionate mărimea şi coloraţia. Ilustratele preluate din alte publicaţii trebuie să fie însoţite de permisiunea autorului. Ilustraţiile color nu pot fi reproduse color decât pe cheltuiala autorului.

PAGINA DE BIBLIOGRAFIE

Referinţele bibliografice trebuie numerotate consecutiv, în ordinea în care ele sunt menţionate pentru prima oară în text şi se vor redacta cu Font Size – 10. Asiguraţi-vă că aţi identificat toate referirile bibliografice în text, tabelele sau legendele tabelelor ori figurilor prin cifre arabe scrise la exponent (exemplu: Un alt studiu[18] arată...). Numele prescurtate ale jurnalelor sunt cele conforme cu *Index Medicus.* Pentru articolele obişnuite de jurnale medicale, veţi menţiona toţi autorii atunci când sunt şase sau mai puţini. Atunci când sunt mai mulţi de şase veţi menţiona trei, urmaţi de et al. Stilul în care vă rugăm să faceţi referirile bibliografice rezultă din exemplul de mai jos. Pentru articole din reviste:

1. Blann D.W., Prien S. D.: *Estemation of fetal....*, Am J of Obst and Gynec, 2000, 182 (5): 1117-1120.

ATENŢIE: Referinţele bibliografice vor fi proporţionale ca număr cu mărimea articolului.

ANUNȚ ABONAMENTE

ROMÂNIA
MINISTERUL APĂRĂRII
DIRECȚIA MEDICALĂ A MINISTERULUI APĂRĂRII
ASOCIAȚIA MEDICILOR ŞI FARMACIŞTILOR MILITARI

Revista de Medicină Militară
Direcția Medicală a Ministerului Apărării
Str. Institutul Medico - Militar, Nr.3-5, Bucureşti, sector 1, cod 010919

Abonamentul la **REVISTA DE MEDICINĂ MILITARĂ** pentru anul 2007 este de 25 RON exemplarul/trimestru.

Un abonament anual costă 100 RON (4 x 25 RON).

Abonamentele se vor face pentru toate cele 4 numere ale revistei şi la depunerea banilor în contul de mai jos se va specifica: abonament la RMM/2007.

Pentru abonare se va proceda astfel: sumele se vor depune în contul Asociației Medicilor şi Farmaciştilor Militari din România:

RO52ARBL200000101314RO01
ANGLO-ROMANIAN BANK LIMITED, Bucureşti.

Codul fiscal al AMFMR este: **18375607**

După virarea banilor, **se vor trimite adrese la redacția Revistei de Medicină Militară** în care se va specifica numărul de abonamente, anexându-se obligatoriu în copie şi documentul care să ateste virarea banilor în contul de mai sus (chitanță F 16, ordin sau dispoziție de plată).

Diverticulul epifrenic

Col.dr. Constantin GROZAVU, Dr. Mihai ILIAŞ, Dr. Aurora FERA, Lt.dr. Marin DRAGOŞ, Dr. Dan ANGELESCU

Secţia Clínică Chirurgie Toracică - Spitalul Clinic de Urgenţă Militar Central „Dr. Carol Davila”

REZUMAT. Diverticulii epifrenici sunt cei mai frecvenţi diverticuli de corp esofagian (20% din totalul diverticulilor esofagieni). Prevalenţa reală nu este cunoscută datorită numărului mare de cazuri asimptomatice, care sunt descoperite întâmplător. Majoritatea bolnavilor au peste 50 de ani, în special decadele şapte şi opt, şi predomină sexul masculin. Odată descoperit şi în prezenţa unei simptomatologii corespunzătoare, indicaţia de elecţie este operatorie, diverticulectomie, esomiotomie extramucoasă extinsă. Efectuarea de rutină a unui procedeu antireflux (Belsey Mark IV) este încă controversată şi de aceea se practică doar când se pune în evidenţă reflux gastroesofagian sau hernie hiatală. Manometria preoperatorie devine obligatorie pentru a stabili cu exactitate tipul intervenţiei chirurgicale. Abordul minim invaziv este încă la început, şi în prezent sunt date relativ puţine datorită experienţei limitate. Rezultatele postoperatorii sunt foarte bune cu dispariţia simptomatologiei cu condiţia efectuării corecte a timpilor operatori.

Cuvinte cheie: diverticul epifrenic manometrie esofagiană diverticulectomie

ABSTRACT. Epiphrenic diverticula are the most common type of esophageal body diverticulum (20% of total esophageal diverticula). Real prevalence is not known, because there are many asymptomatic patients, which are discovered accidentally. Most of the patients are older than 50 years, and this condition present s especially during the seventh and eight decades of life, and is more frequent in men. Once it is diagnosed, in the presence of a adequate simptomatology, the treatment of choice is surgical: diverticulectomy, extended esophageal myotomy. Performing routine Belsey Mark IV antireflux procedure in this patients is controversial, and the patients undergo this operation, only when there is an evidence of gastroesophageal reflux or hiatal hernia. Preoperative manometry become compulsory for choosing the exact type of surgical intervention. The minimally invasive aproach is yet at beginning and in our days there are few results about this aproach because the lack of experience. Postoperative results are very satisfactory, with absence of the simptomatology, only on condition that the steps of the surgical intervention are performed correctly.

Diverticulii esofagieni se pot dezvolta la orice nivel al esofagului, dar etiologia, simptomatologia şi abordul lor chirurgical au condus la clasificarea diverticulilor esofagieni în trei grupe: faringoesofagian, parabronhial şi epifrenic. O a patra grupă – diverticuloza intramurală difuză – este descrisă, dar este destul de rară.

Din punct de vedere histopatologic, diverticulii esofagieni pot fi adevăraţi, care conţin toate straturile peretelui esofagian, şi pseudodiverticuli sau diverticuli „falşi”, formaţi doar din mucoasă şi submucoasă esofagiană.

Diverticulul epifrenic este un diverticul esofagian fals (un fund de sac căptuşit cu mucoasă esofagiană ce herniază prin punctele slabe ale muscularei), un pseudodiverticul al cărui perete este format doar din mucoasă şi submucoasă esofagiană.

Observaţia 1

Pacient în vârstă de 54 de ani se internează în clinica noastră acuzând disfagie pentru solide, dureri retrosternale, pirozis, vărsături postprandiale tardive, tuse iritativă nocturnă, scădere ponderală (7-8 kg în ultimul an).

Tranzitul baritat eso-gastro-duodenal a evidenţiat în treimea inferioară a esofagului toracic, pe partea stângă, o pungă diverticulară cu dimensiuni de circa 8/10 cm, cu colet larg, stomac cu pliuri îngroşate, bulb edematos, deformat cicatriceal.

Endoscopia digestivă superioară decelează diverticul gigant de 8-10 cm, cu mucoasă cu eroziuni şi conţinut alimentar; pe faţa posterioară duodenală postpiloric crater rotund de 8-10 mm şi adânc de 4-5 mm, înconjurat de mucoasa edemaţiată.

Examenul CT toracic cu substanță de contrast (fig.1, 2) pune în evidență formațiune pseudotumorală ovoidă cu margini regulate, cu dimensiuni de 8/9 cm, cu nivel lichidian, situată în mediastinul posterior, în contact cu esofagul toracic supradiafragmatic pe partea stângă.

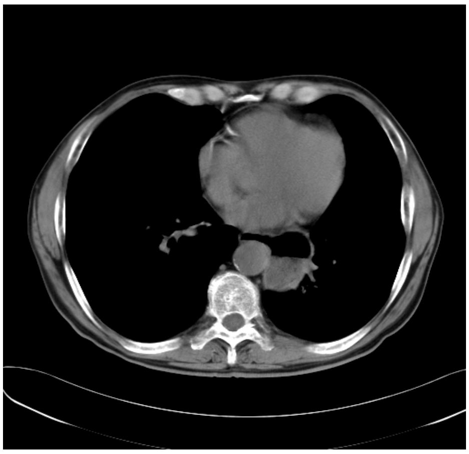

Fig.1. Examen CT:
diverticul esofagian cu nivel lichidian.

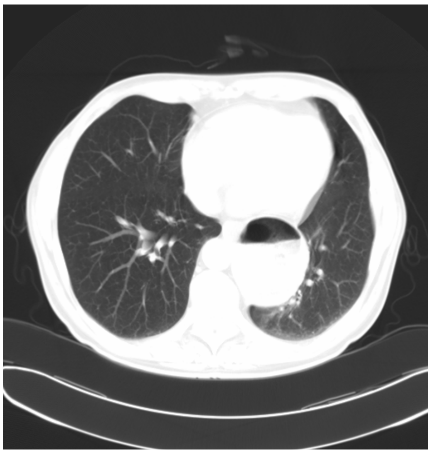

Fig.2. Examen CT:
diverticul esofagian cu nivel lichidian.

Se intervine chirurgical prin toracotomie posterolaterală stângă cu abordul cavității pleurale prin spațiul şapte intercostal. Secționarea ligamentului triunghiular pulmonar şi a pleurei mediastinale pune în evidență la nivelul esofagului inferior toracic o pungă diverticulară de mari dimensiuni, cu fenomene de periesofagită înconjurătoare. Se introduce o sondă Fauchet în esofag şi se disecă atent punga diverticulară, foarte aderentă pe toată lungimea de peretele esofagian (fig 3).

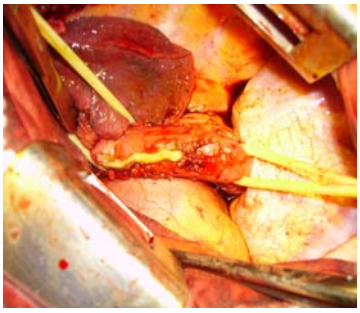

Fig 5. Aspect intraoperator.
Linia de sutură mecanică de la
nivelul peretelui esofagian

Se evidențiază coletul diverticular, cu dimensiuni de circa 5cm, şi se staplează razant la peretele esofagian. Secționarea pe pensă a diverticulului şi îndepărtarea din câmpul operator (fig.4, 5).

Întărirea tranşei de sutură mecanică cu surjet Biocryl 3.0. Esomiotomie extramucoasă pe versantul opus liniei de sutură pe o distanță de circa 6 cm, până la nivelul cardiei (fig.6).

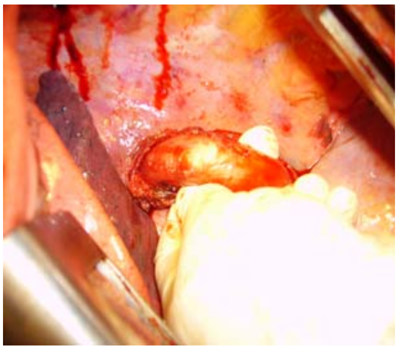

Fig.6. Aspect intraoperator.
Esomiotomie extramucoasă.

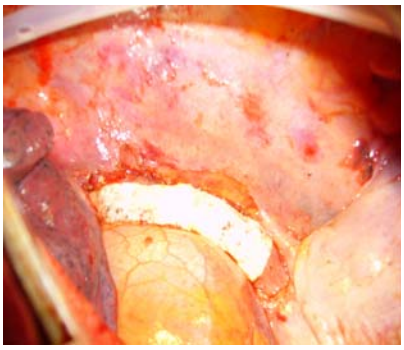

Fig.7. Aspect intraoperator.
Aplicare de TachoSil la nivelul esomiotomiei

Controlul hemostazei, verificarea integrității mucoasei esofagiene şi aplicarea de TachoSil la nivelul liniei de sutură mecanică şi esomiotomiei (fig.7). Se poziționează sonda nazogastrică în stomac, după verificarea integrității mucoasei esofagiene cu albastru de metilen. Drenajul cavității pleurale cu un tub de dren racordat la aspirație pasivă. Toracorafie anatomică.

Evoluția postoperatorie a fost favorabilă, cu reluarea alimentației pe sonda nazogastrică a doua zi postoperator. Suprimarea tubului de dren pleural în ziua a 7-a postoperator şi a sondei nazogastrice în ziua a 5-a postoperator, după control cu substanță radioopacă.

Observația 2

Pacient în vârstă de 62 de ani este transferat în Secția Clinică Chirurgie Toracică cu diagnosticul de diverticul esofagian epifrenic.

Tranzitul baritat esogastric pune în evidență la nivelul esofagului toracic distal o pungă diverticulară cu dimensiuni de circa 2/3 cm (fig.8).

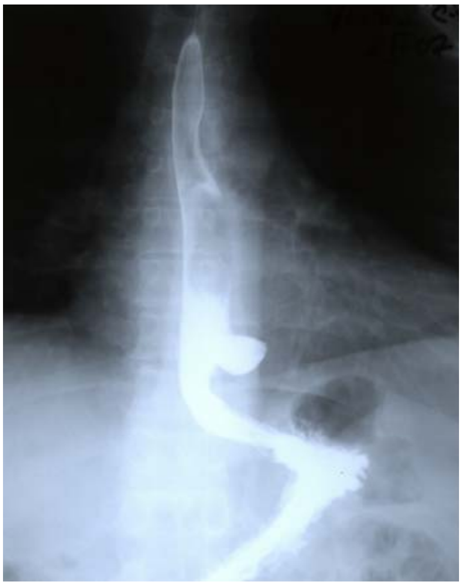

Fig.8 Tranzit baritat esogastric pungă diverticulară epifrenică.

Endoscopia digestivă superioară descrie diverticulul esofagian ca un fund de sac din care se aspiră resturi alimentare (fig.9).

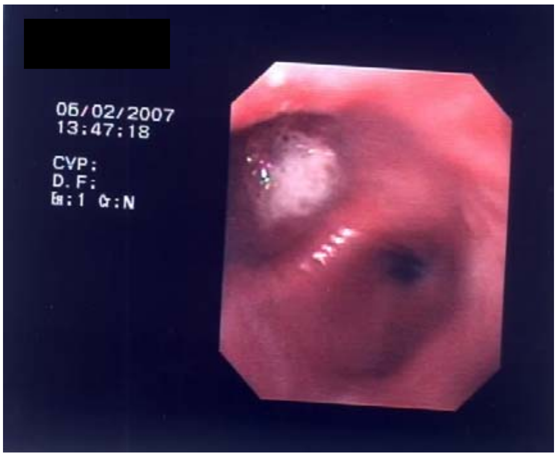

Fig.9 Endoscopie digestivă superioară: fund de sac esofagian inferior, cu resturi alimentare.

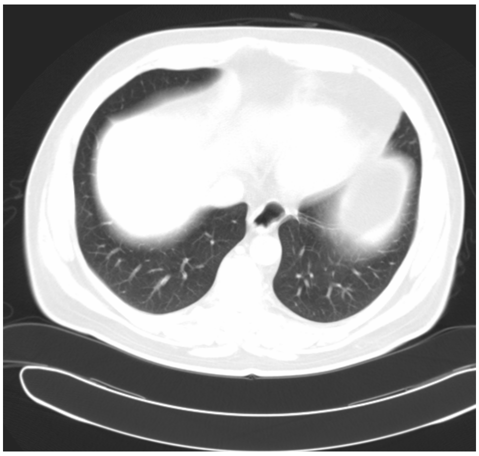

Fig.10. Examen CT: diverticul epifrenic de dimensiuni modeste.

Examenul CT evidențiază diverticulul epifrenic şi exclude eventualele patologii asociate (fig.10).

Atitudinea chirurgicală a fost aceeaşi, cu abordul cavităţii pleurale prin spaţiul şapte intercostal, secţionarea ligamentului triunghiular pulmonar şi a pleurei mediastinale, disecţia esofagului toracic terminal de la nivelul venei pulmonare inferioare până la nivelul hiatusului esofagian diafragmatic, punerea în evidenţa a diverticulului (fig.11).

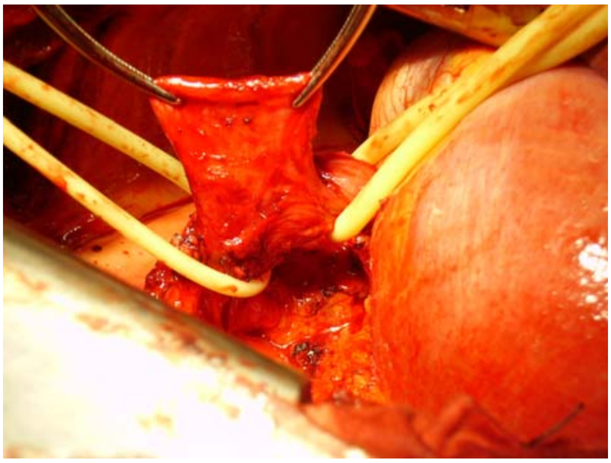

Fig 11. Aspect intraoperator:
disecţia şi evidenţierea diverticulului esofagian

Staplarea diverticulului la nivelul coletului.

Secţionarea diverticulului după staplare la nivelul coletului diverticular (fig.12).

Întărirea tranşei de sutură mecanică cu surjet Biocryl 3.0. Se practică esomiotomie extramucoasă pe versantul opus liniei de sutură pe o distanţă de circa 6 cm pînă la nivelul cardiei. Recalibrarea hiatusului esofagian cu 3 fire pe pilierii diafragmatici (fig.13).

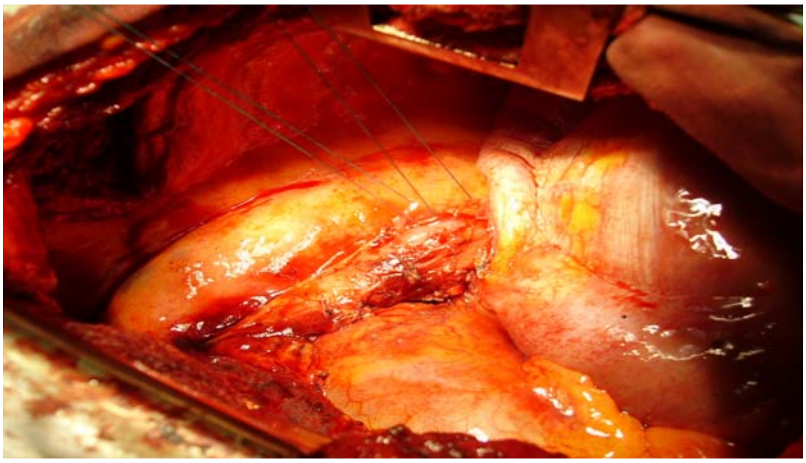

Fig 13. Aspect intraoperator.
Esomiotomie extramucoasă şi recalibrarea hiatusului esofagian

Observaţia 3

Pacientă, în vârstă de 58 de ani, este internată pentru regurgitaţii cu alimente nedigerate şi disfagie moderată. Tranzit baritat: esofag cu tranzit normal până în 1/3 inferioară, unde se evidenţiază un diverticul gigant cu diametrul de 8 cm. Tranzit prin cardia uşor încetinit. Stomac uşor alungit, cu pliuri îngroşate (fig.14, 15).

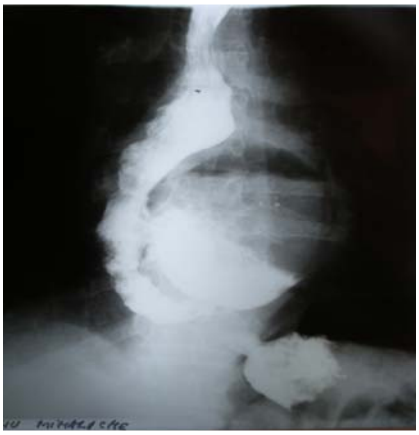

Fig 14. Tranzit baritat:
pungă diverticulară gigantă epifrenică.

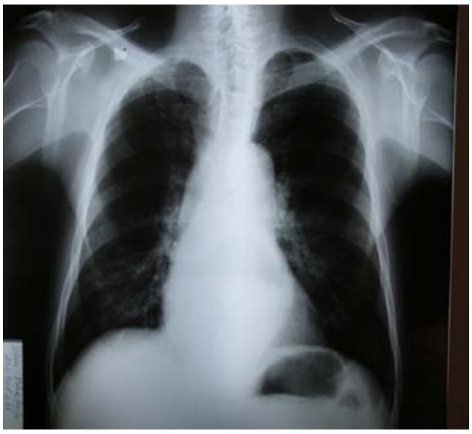

Fig 15. Radiografie toracică:
opacitate retrocardiacă cu nivel lichidian.

Tomografia computerizată cu substanță de contrast administrată oral evidențiază formațiune pseudotumorală de 8/10 cm, epifrenică şi cu comunicare cu esofagul toracic (fig.16, 17).

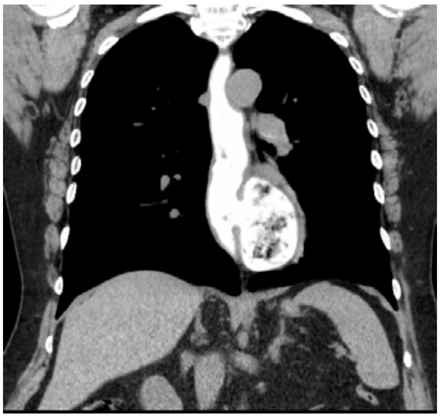

Fig 16. Examen CT cu subst. de contrast adm. oral – pseudotumoră cu nivel lichidian paraesofagian stâng supradiafragmatic.

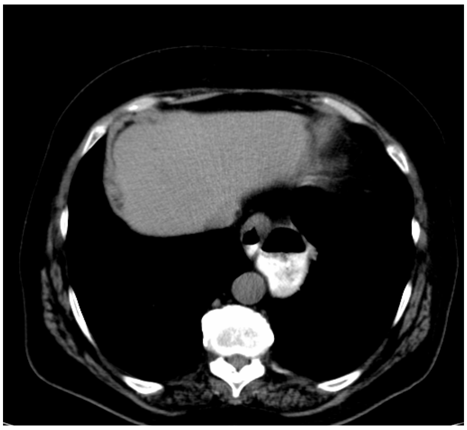

Fig 17. Examen CT cu subst. de contrast adm. oral – pseudotumoră cu nivel lichidian şi comunicare cu esofagul inferior toracic.

Se intervine chirurgical prin toracotomie posterolaterală stângă şi se evidențiază un diverticul esofagian cu diametrul de 10/7 cm, dezvoltat în 1/3 distală a esofagului (fig.18, 19). Se practică diverticulectomie, esomiotomie extramucoasă extinsă subaorto-cardial şi recalibrarea hiatusului esofagian (fig. 20, 21, 22).

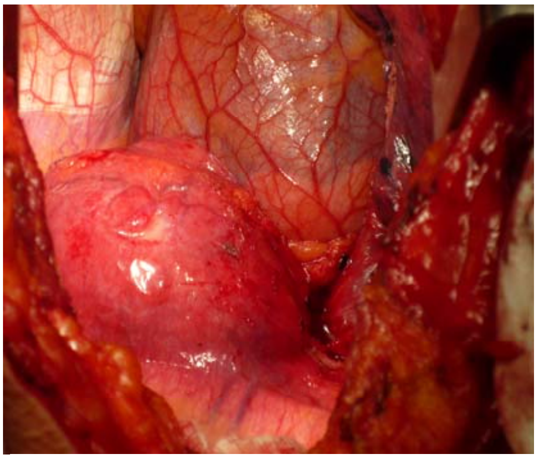

Fig 18. Aspect intraoperator – evidențierea diverticulului esofagian.

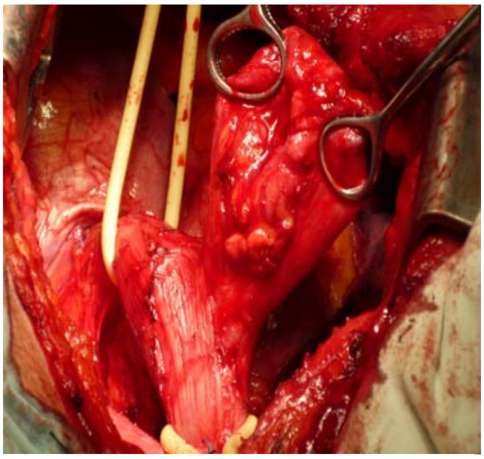

Fig 19. Aspect intraoperator – disecția diverticulului cu evidențierea coletului diverticular.

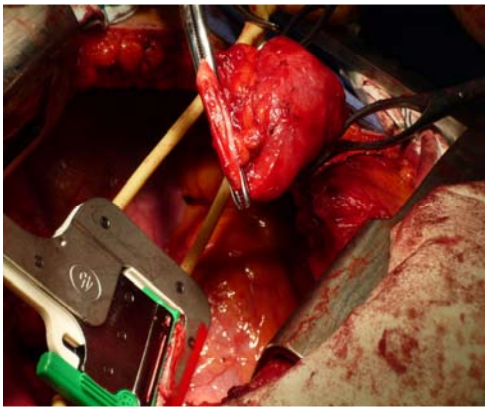

Fig.20. Aspect intraoperator – staplarea şi secționarea diverticulului la nivelul coletului.

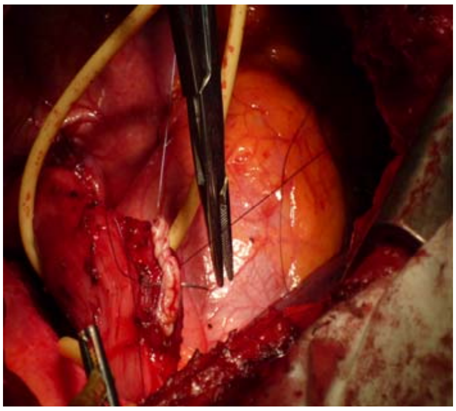

Fig.21. Aspect intraoperator – întărirea tranşei esofagiene cu surjet Biocril 3.0.

Piesa de rezecție se trimite la examen histopatologic (fig.23). Intervenția chirurgicală se termină în mod obişnuit cu drenaj pleural pasiv şi sondă nazogastrică.

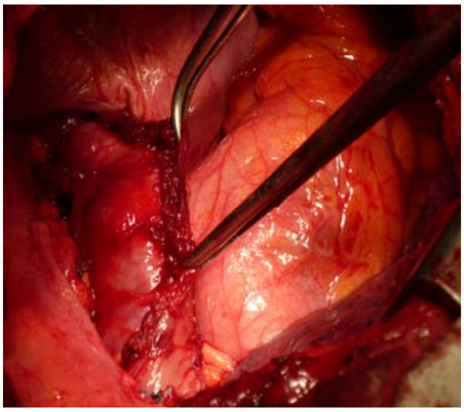

Fig.22. Aspect intraoperator. Esomiotomie extramucoasă subaorto-cardial

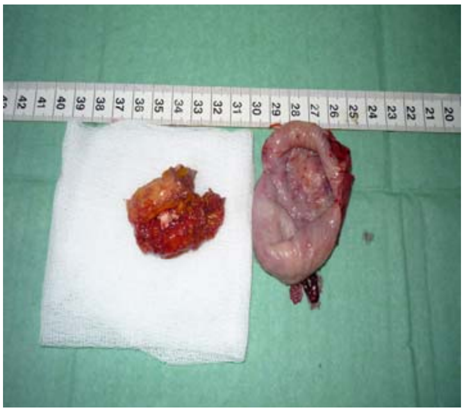

Fig.23. Piesa de rezecție. Diverticul esofagian şi conținutul său

Evoluția postoperatorie a fost favorabilă. Sonda nazogastrică, pe care s-a administrat alimentație corespunzătoare începând din a doua zi postoperator, se suprimă a cincea zi, după un control radiologic cu substanță de contrast.

Discuții

Diverticulul epifrenic este un diverticul esofagian fals (un fund de sac căptuşit cu mucoasă esofagiană ce herniază prin punctele slabe ale muscularei), un pseudodiverticul al cărui perete este format doar din mucoasă şi submucoasă esofagiană.

Diverticulii epifrenici sunt cei mai frecvenți diverticuli de corp esofagian (20% din totalul diverticulilor esofagieni). Prevalența reală nu este cunoscută datorită numărului mare de cazuri asimptomatice care nu sunt descoperite decât întâmplător. Majoritatea bolnavilor au peste 50 de ani, în special decadele şapte şi opt, cu o uşoară predominență a sexului masculin. Conform studiilor din ultimii 40 de ani ai Mayo Clinic, raportul diverticuli epifrenici/ diverticuli Zenker este de 1/5 (Trastek şi Payne, 1989).

Diverticulul epifrenic este un diverticul de pulsiune, luând naştere datorită unui gradient presional ce apare în lumenul esofagian şi care se răsfrânge transmural determinând hernierea mucoasei prin punctele slabe ale muscularei esofagiene. Deşi inițial simptomatologia a fost atribuită exclusiv diverticulului esofagian distal, Vinson (1934) raportează disfuncții ale motilității esofagiene subiacente. Acalazia, spasmul esofagian difuz, hipertonia sfincterului esofagian inferior şi alte anomalii motorii nespecifice au fost toate constatate în asociere cu diverticulul epifrenic.

Introducerea unei tehnici moderne de diagnostic, manometria ambulatorie timp de 24 de ore (Nehra şi colab., 2002), a permis studiul prospectiv al fiziopatologiei diverticulului epifrenic.

Orringer (1993) susţine că tulburările de motilitate esofagiene stau la baza apariţiei tuturor diverticulilor epifrenici. Acest concept, care afirmă că diverticulii epifrenici reprezintă de fapt o complicaţie în evoluţia tulburărilor de motilitate esofagiană mai degrabă decât o slăbiciune a peretelui muscular esofagian, a devenit general acceptat.

Majoritatea pacienţilor sunt asimptomatici, în timp ce restul au de la o disfagie uşoară până la regurgitaţie cu aspiraţie pulmonară. De obicei, diverticulul esofagian este descoperit întâmplător la un tranzit baritat efectuat pentru cu totul alte raţiuni.

Disfagia, durerea toracică, regurgitaţia, tusea nocturnă şi pneumopatia de aspiraţie se datorează mai degrabă disfuncţionalităţii motorii subiacente decât diverticulului epifrenic per se. Regurgitaţia şi aspiraţiile repetate determină pneumonii cu distrucţii însemnate de parenchim pulmonar.

Tranzitul baritat este metoda standard de evidenţiere a diverticulului, dar şi a eventualelor anomalii motorii esofagiene, putând decela şi o posibilă patologie asociată: cancer, hernie hiatală, stenoze esofagiene.

Endoscopia digestivă superioară trebuie efectuată de către endoscopişti cu experienţă şi poate diagnostica esofagitele şi cancerul esofagian, atunci când se suprapun peste patologia deja existentă (cazuri rare). Are un rol important în pregătirea preoperatorie a bolnavilor cu diverticuli voluminoşi, cu fenomene de retenţie şi regurgitaţie, prin îndepărtarea resturilor alimentare de la acest nivel.

Manometria esofagiană este importantă în descoperirea anomaliilor motorii, dar mai ales în indicarea obstrucţiei funcţionale şi a lungimii esomiotomiei ce urmează a fi efectuate.

PH-metria pe 24 de ore este indicată în momentul în care se suspicionează refluxul gastroesofagian şi impune efectuarea unui procedeu chirurgical antireflux.

Pacienţii asimptomatici şi cei cu o simptomatologie uşoară sunt de obicei trataţi conservativ, intervenţia chirurgicală impunându-se când apar retenţia alimentelor la nivelul pungii diverticulare cu regurgitaţie şi pneumoniile de aspiraţie consecutive. Totuşi părerile sunt împărţite: astfel, dacă Benacci şi colegii (1993) apelează la chirurgie în funcţie de mărimea, poziţionarea diverticulului dar şi de simptomatologie, Altorki şi colab. (1993) propun chirurgicalizarea tuturor pacienţilor cu diverticul epifrenic, pentru a preveni posibilele complicaţii.

Prima diverticulectomie a fost efectuată de Clairmont (1927), folosind calea de abord extrapleurală. Barett (1933) a efectuat prima diverticulectomie pe cale transpleurală. Tehnica chirurgicală curentă este cea prin toracotomie posterolaterală stângă, cu abordul cavităţii pleurale prin spaţiul şapte intercostal, disecţia sacului diverticular, diverticulectomie şi esomiotomie extramucoasă. Esomiotomia este necesară nu doar pentru a preveni apariţia fistulei esofagiene, ci şi pentru a ameliora simptomatologia datorată prezenţei tulburărilor de motilitate esofagiană asociate.

Esomiotomia se efectuează pe partea opusă diverticulectomiei şi trebuie extinsă câţiva milimetri pe stomac şi cranial până la nivelul venei pulmonare inferioare sau până la nivelul unde în timpul efectuării manometriei au fost semnalate tulburări de motilitate esofagiene. Unii chirurgi, precum Belsey (1966) sau Little (1988), au propus ca procedeu chirurgical adiţional esomiotomiei şi efecturea unei valve antireflux. Efectuarea de rutină a unui procedeu antireflux este încă controversată şi de aceea mulţi chirurgi îl practică doar atunci când preoperator se pune în evidenţă prezenţa refluxului gastroesofagian sau hernie hiatală. Procedeul antireflux de elecţie este Belsey Mark IV.

Recent au fost propuse tehnici chirurgicale miniinvazive în tratamentul diverticulului esofagian. Abordul toracoscopic – Rosati (1998), Van Der Peet (2001) şi laparoscopic – Rosati. Rolul toracoscopiei şi laparoscopiei în tratamentul diverticulului esofagian epifrenic rămâne să fie stabilit, în prezent existând date relativ puţine datorită experienţei limitate şi urmăririi pe termen lung a acestor rezultate.

Imagistica prin rezonanță magnetică în evaluarea leziunilor traumatice ale gleznei

Gl. bg. (r) prof. univ. dr. Ioan CODOREAN*, Col. şef lucrări dr. Dragoş CUZINO*,
Mr.asist.univ.dr. Ionuț Bogdan CODOREAN, Medic rezident Gabriela Simona TOMA***

Spitalul Clinic de Urgență Militar Central "Carol Davila", Bucureşti
***Clinica de Radiologie, Imagistică Medicală şi Medicină Nucleară, **Clinica de Ortopedie şi Traumatologie**

REZUMAT. Glezna reprezintă segmentul membrului inferior care uneşte gamba cu piciorul, puțin acoperit de părțile moi, dar mult solicitat în statică şi locomoție. Datorită complexității structurilor anatomice ale gleznei, nevizualizabile prin tehnici radiologice şi scintigrafice, IRM rămâne metoda de elecție pentru vizualizarea multiplanară.

Cunoaşterea aspectului IRM normal al gleznei are o mare importanță în identificarea corectă a structurilor osteo-ligamento-tendinoase şi a patologiilor acestora. Având în vedere că în anumite activități sportive glezna şi în special tendoanele sunt foarte expuse, am efectuat un studiu retrospectiv IRM pe un lot de 170 de pacienți în scopul identificării şi evaluării leziunilor traumatice. Examinarea IRM a evidențiat leziuni pluritendinoase în majoritatea cazurilor. Dintre acestea cele mai multe au fost leziunile tendonului lui Ahile (predominant rupturi parțiale) şi leziunile flexorului lung al halucelui. S-au identificat şi alte leziuni tendinoase dar în procente mai mici.

În studiul nostru am folosit un aparat de rezonanță magnetică de 1T. Pacienții au fost poziționați în decubit dorsal cu piciorul de examinat în flexie plantară. Achizițiile s-au făcut în cele trei planuri: axial, sagital şi coronal, folosindu-se secvențele T1 SE, T2 SE, T1 TIRM, PD FS, T2 fl2D şi T2 de3D, cu secțiuni de 3 mm grosime şi un FOV de 16 cm.

Examenul IRM reprezintă o tehnică de elecție pentru vizualizarea multiplanară a tendoanelor şi a relațiilor acestora cu structurile din jur.

Cuvinte cheie: glezna, IRM, tendoane, tendonul lui Ahile, flexorul lung al halucelui

ABSTRACT. The ankle is a lower limb segment that joints the ankle with the foot, slightly covered by the soft tissues, but very much used while standing and in motion. Due to anatomical complexity of the ankle, not shown by radiography and scintigraphy, MRI remains the primary method for multiplanar imaging.

A good knowledge of the normal MRI aspect of the ankle has a great importance for a proper identification of the bony-meniscal-ligamentar lesions and their pathologies. Considering that in some sport activities the ankle and especially the tendons are very exposed to traumatic lesions, we have made a MRI retrospective study on a lot of 170 patients to identify and evaluate these lesions. The MRI exam showed associated tendinous lesions in most of the cases. Most of these lesions were injuries of the Achilles tendon (especially partial tears) and injuries of the flexor hallucis longus. We identified other tendinous lesions too but in a smaller percentage.

We used in our study a magnetic resonance machine of 1T. Patients were placed in supine position, with the examined foot in plantar flexion. The acquisitions were made in three planes (sagittal coronal and axial), using the T1 SE, T2 SE, T1 TIRM, PD FS, T2 fl2D and T2 de3D sequences, with 3 mm thick sections and a 16 cm FOV.

The MRI exam is the main technique for a multiplanar imaging of the tendons and their relations with the surrounding structures.

Glezna reprezintă segmentul membrului inferior care uneşte gamba cu piciorul, puțin acoperit de părțile moi, dar mult solicitat în statică şi locomoție. Aceasta este alcătuită din structuri anatomice complexe, nevizualizabile prin tehnici radiologice şi scintigrafice, astfel că IRM rămâne metoda de elecție pentru vizualizarea multiplanară.

În atletism, fotbal, basket, tenis, patinaj, hockey, precum şi în alte activități sportive şi de dans, glezna este suprasolicitată fie prin dorsiflexia forțată a piciorului contra muşchilor gambei contractați, fie prin hiperflexia plantară, prin schimbări rapide de picior, prin respingeri repetate de pe antepicior sau doar prin suprasolicitare.

Elemente de anatomie şi biomecanică ale gleznei

Din punct de vedere anatomic, glezna este un complex osteo-ligamento-tendinos compus din:

– structuri osoase;

– capsula şi sinoviala, ce cuprind articulația gleznei;

– structuri ligamentare şi tendinoase: împărțite în patru compartimente: anterior, posterior, lateral şi medial

Un rol foarte important îl are tendonul lui Ahile, din compartimentul posterior. Acesta este mărginit anterior de bursa retrocalcaneană şi de grăsimea Kager şi posterior de bursa calcaneană subcutanată. Este un tendon puternic, având o grosime de 4-6 mm, plat sau concav anterior în secțiune axială. La 2-6 cm deasupra inserției pe calcaneu prezintă o zonă slab vascularizată, fapt pentru care aici este locul de elecție al leziunilor.

Tendoanele sunt alcătuite din fibrile de colagen învelite în endotenon, formând mănunchiuri, acoperite la periferie de epitenon. Majoritatea tendoanelor sunt cuprinse la exterior într-o fascie, cu excepția tendonului lui Ahile, care e acoperit de peritenon, format din trei straturi (parietal, visceral şi mezotenonul între ele).

Din punct de vedere biomecanic, glezna are dublu rol: static şi dinamic. Prin rolul static păstrează echilibrul gambei pe picior iar prin cel dinamic realizează mişcările piciorului în mers de dorsiflexie, cu uşoară inversiune (ridică marginea medială a piciorului) şi o amplitudine de 15-20°, precum şi de flexie plantară cu uşoară eversiune (coboară marginea medială a piciorului) şi o amplitudine de 45°.

Anatomia IRM a gleznei

Cunoaşterea aspectului IRM normal al gleznei are o mare importanță în identificarea corectă a structurilor osteo-ligamento-tendinoase precum şi a patologiilor însoțitoare ale acestora. În acest studiu vom insista asupra tendoanelor gleznei, structuri deosebit de importante şi uşor de identificat cu ajutorul rezonanței magnetice. Ele sunt urmărite în toate cele trei planuri, axial, sagital şi coronal.

În plan axial putem identifica cele patru compartimente ale gleznei:

A. anterior:

a) tendonul **t**ibial anterior **(TA)**

b) tendonul **e**xtensor lung al halucelui **(ELH)**

c) tendonul extensor lung al **d**egetelor **(ELD)**

B. medial:

a) tendonul **t**ibial posterior **(TP)**

b) tendonul flexor lung al **d**egetelor **(FLD)**

c) tendonul flexor lung al **h**alucelui **(FLH)**

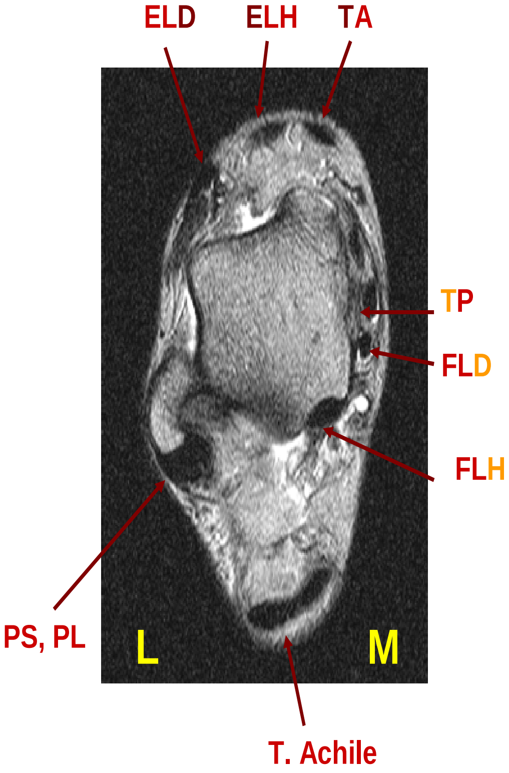
C. lateral:

a) tendonul peronier scurt **(PS)**

b) tendonul peronier lung **(PL)**

D. posterior

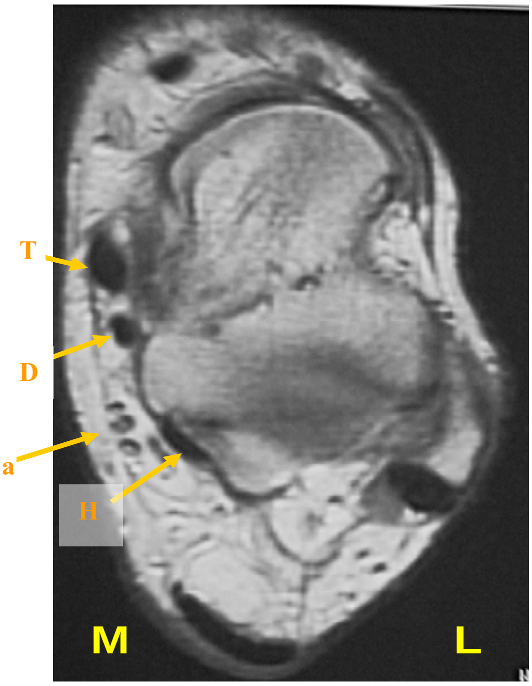
- tendonul lui Ahile



Deoarece planul axial este foarte important în identificarea compartimentelor şi a tendoanelor din acestea, modificările de contur dar şi cele de semnal intra- şi peritendinos, este necesară o bună cunoaştere a acestuia. Astfel, tendoanele compartimentului anterior se pot reţine uşor cu formula **TED**, iar ale celui medial folosind formula mnemotehnică **TDAH (Tom Dick and Harry)**

Compartimentul medial
Tom Dick and Harry
- **T**ibial posterior - **T**
- flexor lung al **D**egetelor - **D**
- **a**rtera, vena şi nervul tibial posterior - **a**
- flexor lung al **H**alucelui - **H**
- **T = 2 D** sau **2 H**

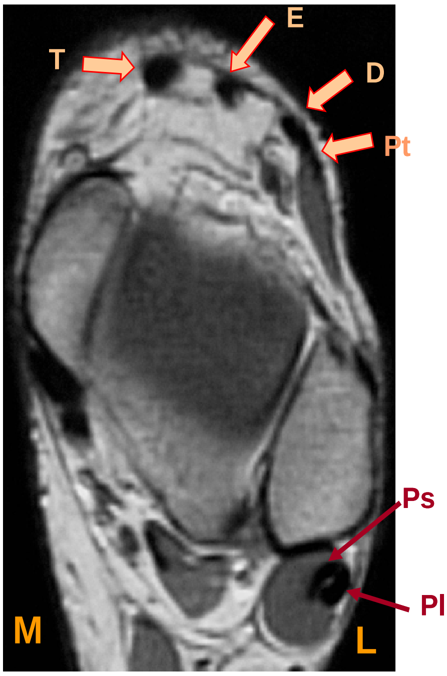
M = medial
L= lateral



De asemenea, compartimentul anterior se reţine mai uşor cu ajutorul formulei **TED**:

Compartimentul anterior
TED
- **T**ibial anterior
- **E**xtensor lung al halucelui
- Extensor lung al **D**egetelor
- *Peroneus tertius* (parte din extensorul lung al degetelor) (Pt)

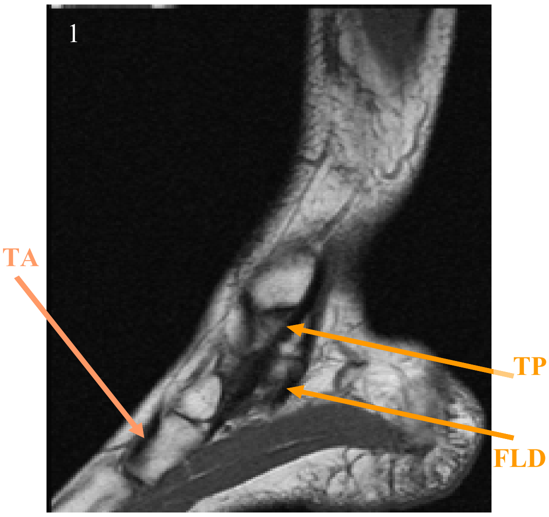
Compartimentul lateral
- Peroneul scurt (**Ps**)
- Peroneul lung (**Pl**)

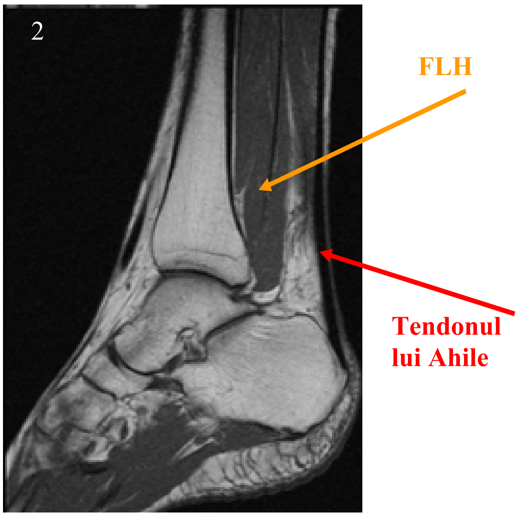


Compartimentul lateral cuprinde cei doi peronieri: peroneul scurt, de partea medială şi cel lung, de partea laterală.

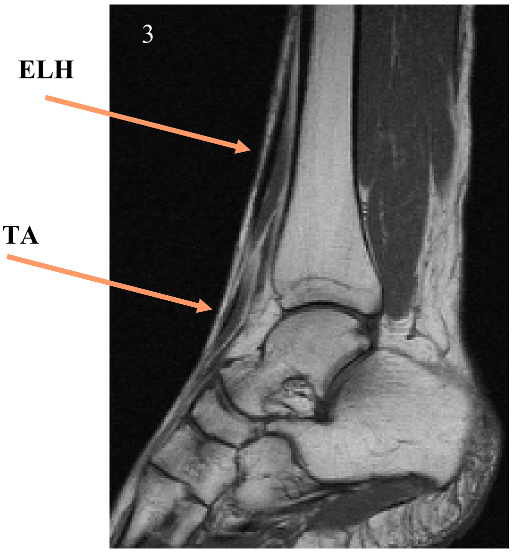
Planul sagital este util în urmărirea traiectului tendinos în lungime, precum şi contururile anterior şi posterior, pe lângă modificările de semnal. Este important să coroborăm rezultatele obținute în plan axial cu cele din plan sagital pentru confirmarea diagnosticului imagistic.

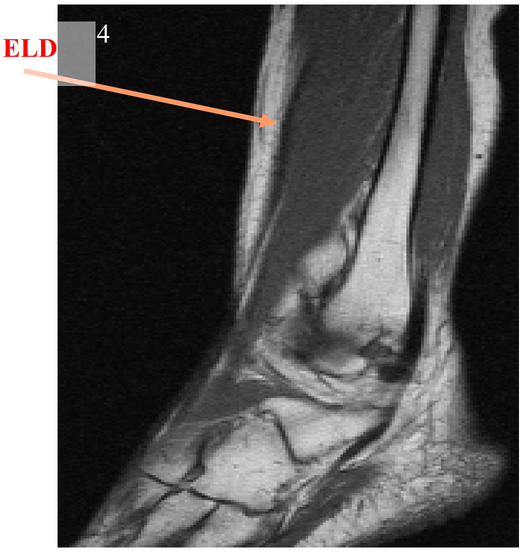
Plecând dintr-un plan parasagital medial înspre lateral, putem identifica tendoanele după cum urmează: anterior se observă tendonul tibial anterior, iar posterior cele două tendoane din compartimentul medial, tibial posterior şi flexorul lung al degetelor (1).



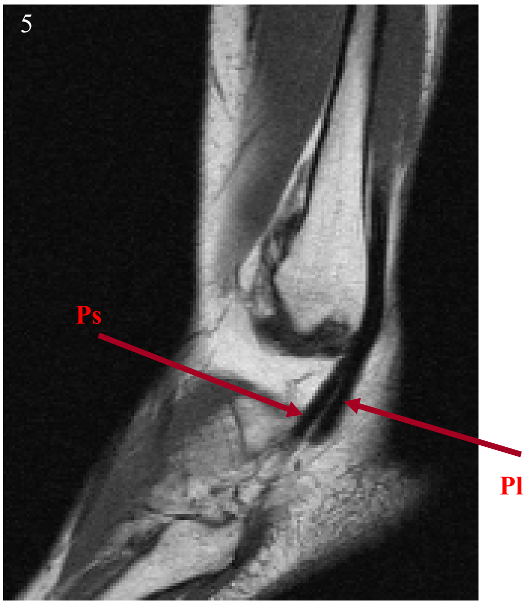


Posterior de flexorul lung al degetelor, tot în compartimentul medial se află tendonul flexor lung al halucelui. Acesta este mărginit posterior de grăsimea Kager şi de tendonul lui Ahile din compartimentul posterior (2).





Dintre tendoanele compartimentului anterior mai putem observa anterior (3) o parte din tibialul anterior (TA) şi începem să vedem tendonul extensor lung al halucelui (ELH); pe următoarea imagine (4) se observă şi cel mai lateral tendon din acelaşi compartiment, extensorul lung al degetelor (ELD).



Compartimentul lateral cuprinde două tendoane: peronierul scurt (Ps), aflat medial şi peronierul lung (Pl), cel mai lateral.

Studiul nostru

Am realizat un studiu retrospectiv pe un lot de 237 de pacienți, în perioada septembrie 2004 – octombrie 2008, dintre care am selectat 170, 145 bărbați şi 25 femei, cu vârste cuprinse între 16 şi 67 ani, la care examenul radiologic a fost normal sau neconcludent.

Tehnica de lucru

Am utilizat un aparat Siemens, Magnetom, Harmony de 1T. Pacientul a fost poziționat în decubit dorsal cu piciorul de examinat în flexie plantară 20° sau hiperflexie pentru vizualizarea tendonului ELD ("efectul de unghi magic").

Antena folosită a fost una flexibilă, de suprafață, cu piciorul controlateral în afara FOV; se poate utiliza şi o antenă cadru pentru examinarea ambelor glezne.

Secvențele şi incidentele utilizate

Am folosit secvențele convenționale T1 SE şi T2 SE, secvența de inversie T1 TIRM, secvența PD FS, secvențele de gradient T2 fl2D şi T2 de3D, cu secțiuni de 3 mm grosime, în incidențele axială, coronală, sagitală şi un FOV de 16 cm.

Protocolul de examinare se poate modifica şi în funcție de patologia întâlnită.

Rezultate

La cei 170 de pacienți la care examenul radiologic a fost normal sau neconcludent, leziunile pluritendinoase au fost majoritare – 65,88%, cele monotendinoase fiind mai reduse – 26,47%. Leziunile de tendoane s-au asociat şi cu leziuni ligamentare (28,82%), leziuni de edem osos (18,23%) şi cu leziuni musculo-aponevrotice (14,7%). Alte leziuni importante întâlnite în studiul nostru sunt cele osteocondrale talare (15,88%).

Dintre afectările tendoanelor, cele ale tendonului lui Ahile au fost cele mai numeroase (61,76%), majoritatea fiind rupturi parțiale (37,64% dintre afectările ahilene), cele totale fiind într-un procent mult mai mic, 5,88%. Am întâlnit de asemenea într-un procent semnificativ leziuni de flexor lung al halucelui (22,94%). Restul leziunilor tendinoase au fost în procente mai mici.

Leziune		Nr.	Total pacienți
Tendonul lui Ahile 105 (61,76%)	**Ruptură parțială**	64(**37,64%**)	170
	Ruptură totală	10 (5,88%)	170
	Tendinite, para- şi peritendinite	23(13,52%)	170
	Tendinoză	8(4,70%)	170
FLH		39(**22,94%**)	170
TP		12 (7,05%)	170
FLD		11(6,47%)	170
PL		8(4,70%)	170
PS		6(3,52%)	170

Rupturile tendonului lui Ahile (după *Magnetic Resonance Imaging in Orthopaedics and Sports Medicine* – David W. Stoller):

Tipul I – ruptură parțială ≤ 50%, pe fața anterioară sau pe cea posterioară.

Tipul II – ruptură totală, fie cu suprapunerea celor două capete tendinoase, fie cu retracția acestora şi apariția unui spațiu intertendinos ≤ 3 cm.

Tipul III – ruptură totală, cu un spațiu intertendinos 3 – 6 cm.

Tipul IV – ruptură totală, cu un spațiu intertendinos > 6 cm (rupturi neglijate).

Clasificarea rupturilor e foarte importantă deoarece orientează conduita terapeutică.

Rupturile se mai clasifică în:

► acute => 0-4 săptămâni;

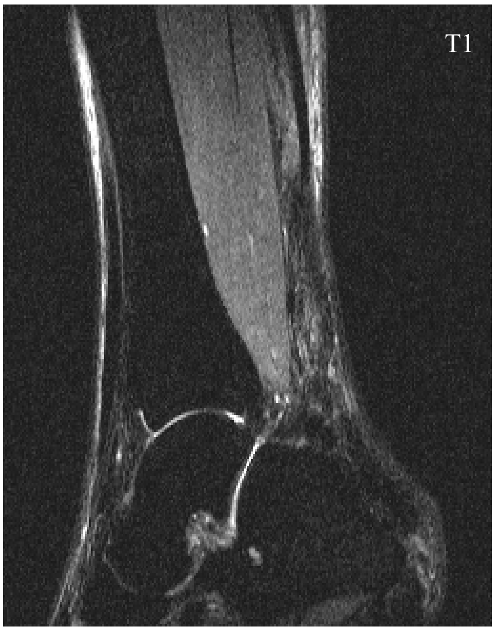
► cronice => 1-3 luni.

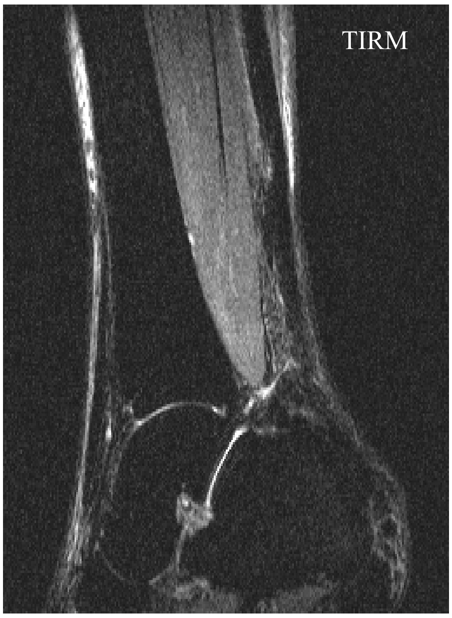
În continuare vom exemplifica această clasificare prin cazuistica existentă în clinica noastră.

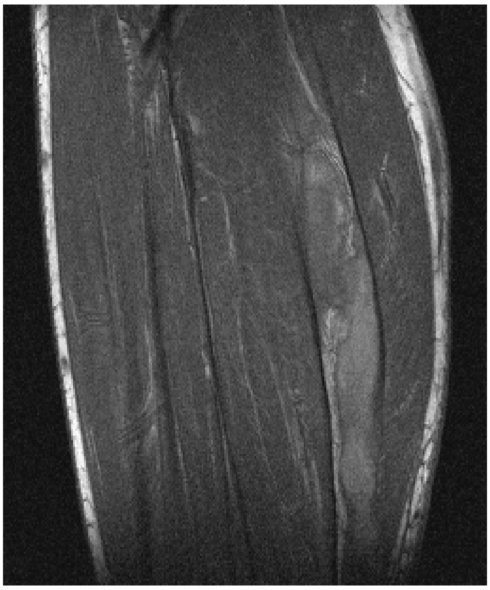
Ruptura parțială a tendonului lui Ahile

Aspectul IRM (incidențele sagitală şi axială)

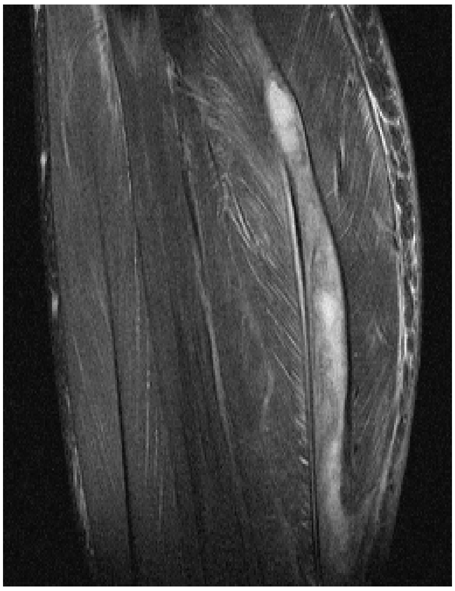
1. arii intratendinoase lineare/ focale cu semnal crescut;
2. îngroşarea/ ondularea fibrelor fără spațiu intertendinos;
3. continuarea parțială a fibrelor tendonului pe imaginile sagitale;
4. ruptura parțială acută (hipersemnal T2 şi TIRM) suprapusă pe o tendinita ahileană cronică (semnal intermediar -scăzut).





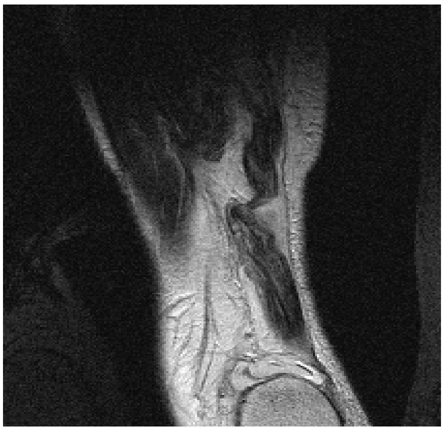


T1 SE

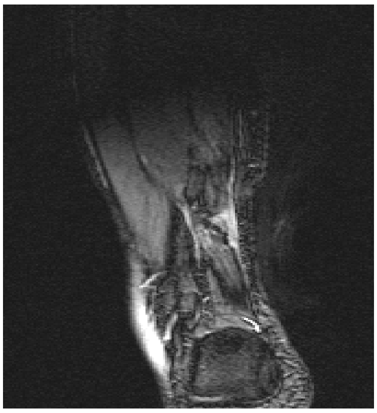


T2 SE FS

Cazul 1
N.R. 29 ani
Dg. trimitere: Traumatism gamba dr.
IRM: Pe secvențele: T1 TIRM sag. se evidențiază tendonul ahilean îngroşat, cu contur anterior neregulat şi cu modificări de semnal, predominant crescut pe un segment de 3 cm, sugestiv pentru infiltrație edematoasă. La nivelul gambei prezintă între mm. gastrocnemian şi solear o arie fusiformă cu semnal crescut T1SE şi hipersemnal T2 SE FS, dată de un hematom.

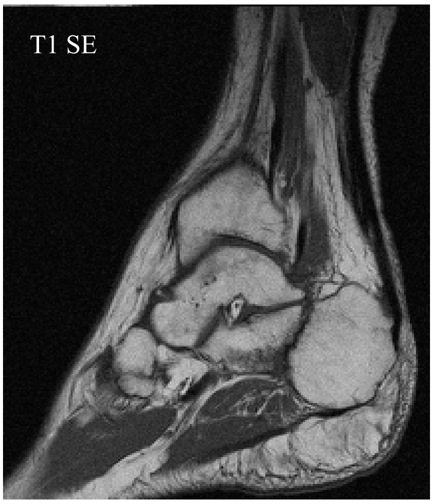


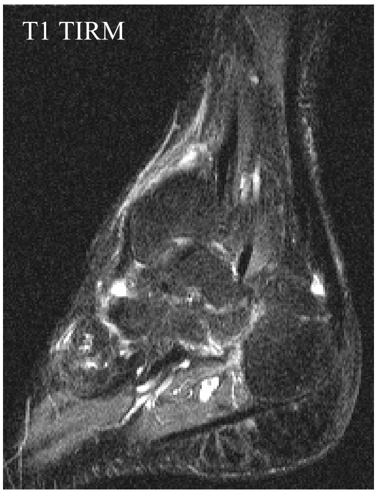
PD T2 TSE



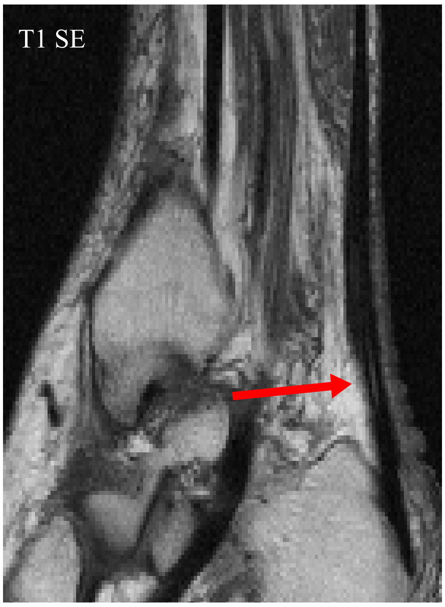
T2*

Cazul 2
F.A., 31 ani
Tendonul lui Ahile apare cu traiect angulat, îngustat, ondulat, cu semnal neomogen intratendinos, predominant crescut. În secvenţa T2* se evidenţiază o acumulare fluidă la nivelul focarului de ruptură. Sunt modificări subacute (3 săptămâni) de ruptură parţială de tendon ahilean.





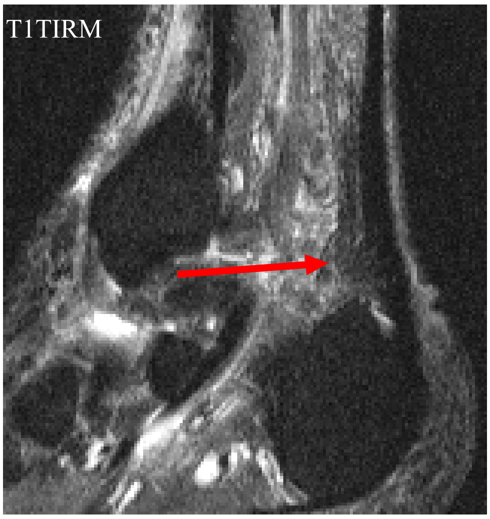
Cazul 3
T.M., 40 ani
Acest pacient a suferit un traumatism sever de gleznă şi picior. Examenul radiografic a arătat prezenţa fracturilor de calcaneu şi de maleolă peronieră. Datorită severităţii traumatismului s-a efectuat şi un examen IRM care a identificat în plus, pe T1SE, tendonul lui Ahile îngroşat, cu contur anterior neregulat, întrerupt şi o mică arie în hiposemnal anterior de acesta la nivelul inserţiei pe calcaneu. Secvenţa T1TIRM confirmă ruptura parţială anterioară a tendonului lui Ahile şi bursită retrocalcaneană (în hipersemnal).

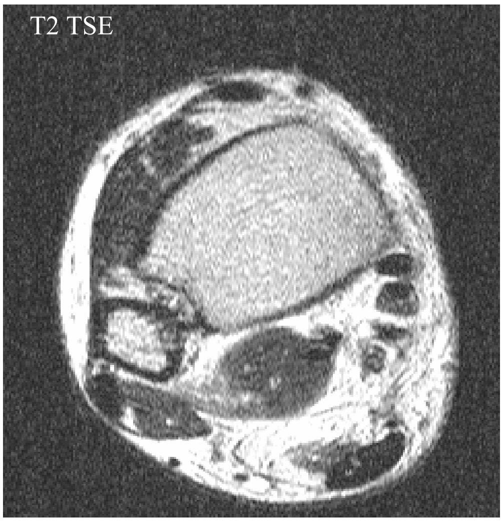


Cazul 4

M.D., 52 ani

Pacientul, care suferise un traumatism de gleznă dreaptă în urmă cu mai mult de o lună, a revenit la control. Examenul IRM a arătat tendonul lui Ahile îngroşat, cu contur neregulat anterior şi o imagine fusiformă cu semnal crescut intratendinoasă pe secvenţa T1 SE. Pe secvenţa de inversie observăm grăsimea Kager neomogenă, cu semnal predominant crescut, aspect sugestiv de infiltraţie fibro-adipoasă. Imaginea în plan axial confirmă modificările menţionate anterior de ruptură cronică parţială de tendon ahilean şi infiltraţie fibro-adipoasă a grăsimii Kager.





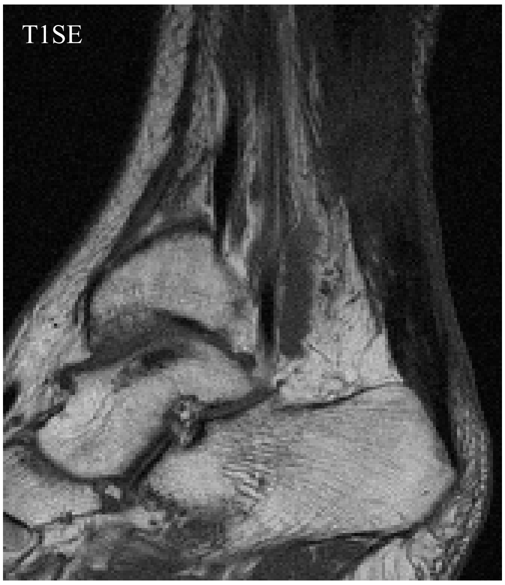
Ruptura totală a tendonului lui Ahile

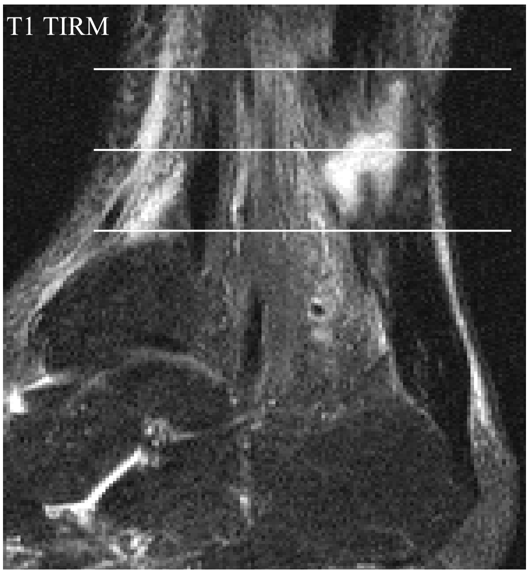
Aspectul IRM:

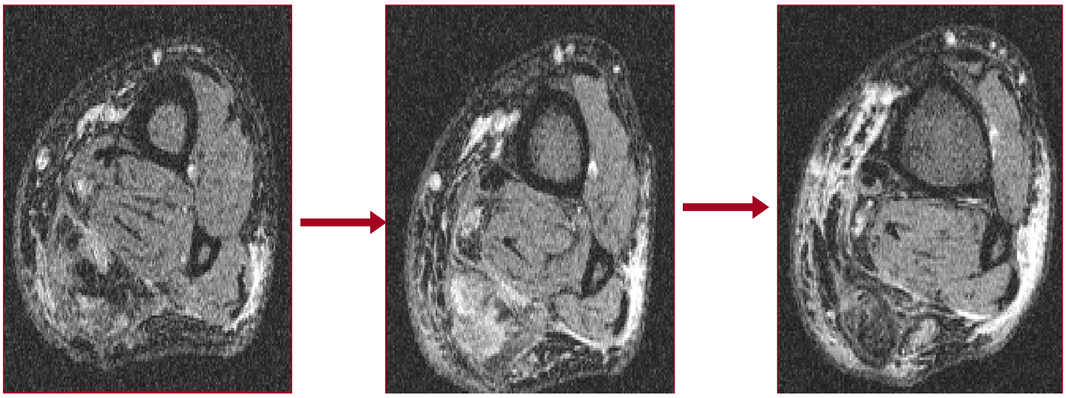
- discontinuitate cu retracţia şi deşirarea capetelor tendinoase;
- T2*, T2 FS TSE, TIRM – arată prezenţa edemului şi a hemoragiei;
- faza acută: edem / hemoragie în spaţiul intertendinos şi peritendinos;
- faza cronică: ţesut cicatriceal hipointens sau grăsime hiperintensă în spaţiul intertendinos.

Aspectul RM postoperator:

- punte fibroasă de consistenţă mică între capetele rupte ale tendonului;
- aspect bulbos al capetelor rupte şi distanţă mare între acestea (vindecare suboptimă);
- artefacte de sutură în hipersemnal T2;
- spaţii fluide intratendinoase la 3-6 luni postoperator în hipersemnal;
- creşterea grosimii tendonului şi scăderea semnalului intratendinos la 12 luni postoperator.







T2 fl 2D

Cazul 5

D.C.A., 39 ani

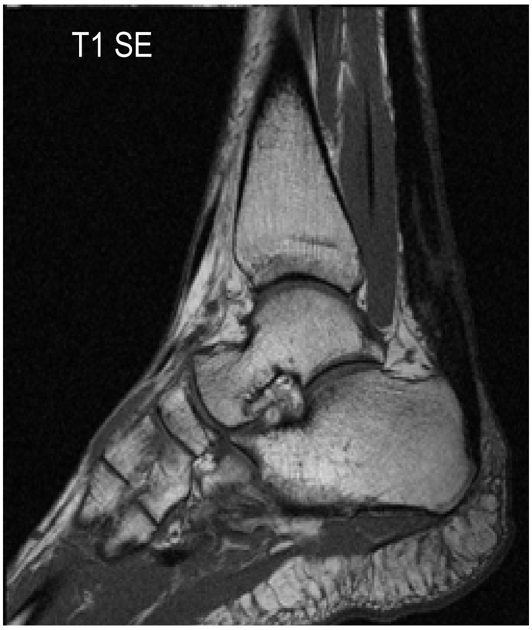
Secvenţa T1SE arată tendonul lui Ahile îngroşat, cu semnal neomogen, iar secvenţa de inversie demonstrează prezenţa rupturii totale a acestuia. Cele două capete tendinoase sunt cu margini neregulate, franjurate, separate de un spaţiu intertendinos de aproape 3 cm, unde se observă o arie în hipersemnal, sugestivă pentru infiltraţia edematoasă. Secvenţele în plan axial la nivelul capetelor tendinoase şi a spaţiului intertendinos demonstrează discontinuitatea tendonului, cu îngroşarea capetelor şi neomogenităţi de semnal la acest nivel.

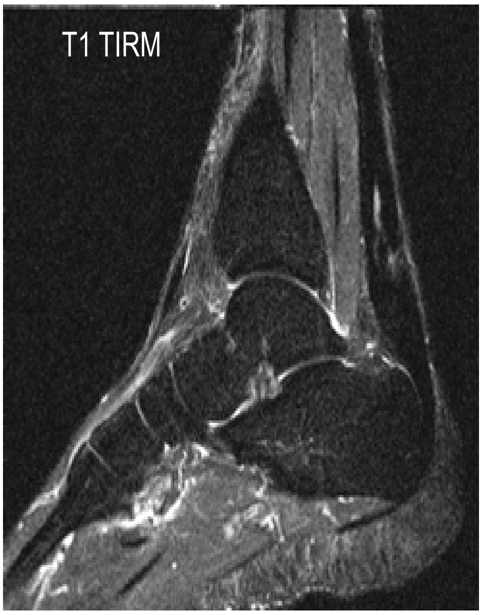
Tendinita ahileană

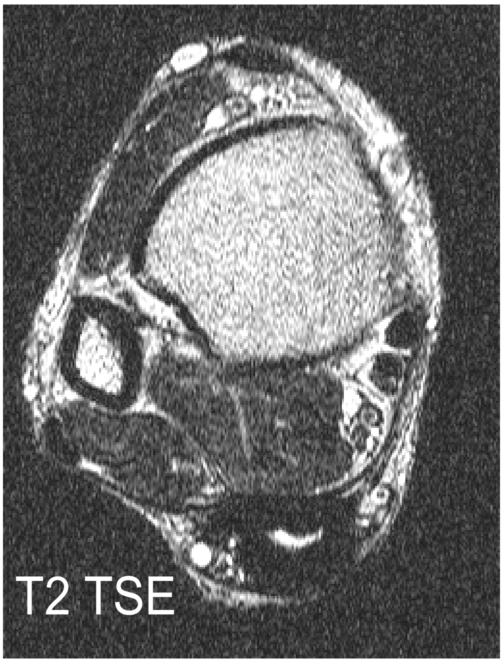
Tendinita = inflamaţie intrinsecă a tendonului ahilean

Aspectul IRM

1. Îngroşare focală / fusiformă / difuză a tendonului lui Ahile pe toate secvenţele.
2. Modificări inflamatorii intratendinoase.
3. Tendonul apare îngroşat şi convex anterior pe incidenţa sagitală.
4. Fluid în bursa retrocalcaneană.







Cazul 6

I.I., 37 ani

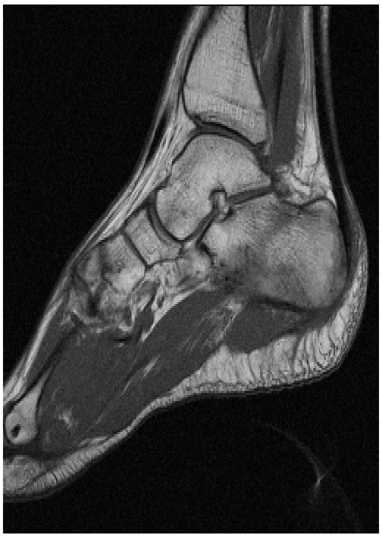
Pacient cunoscut cu traumatism vechi de gleznă dreaptă revine pentru un nou traumatism. Examenul IRM arată tendonul ahilean mult îngroşat, convex anterior, cu zone fusiforme cu semnal crescut intratendinoase.

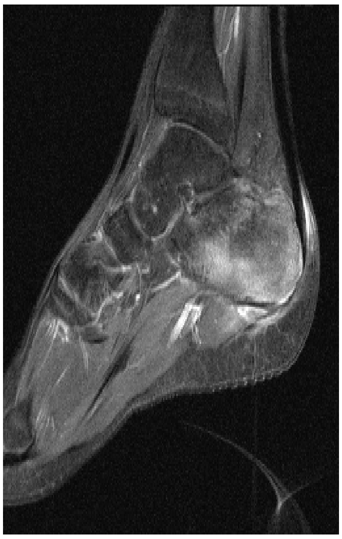
Peritendinita şi paratendinita ahileană

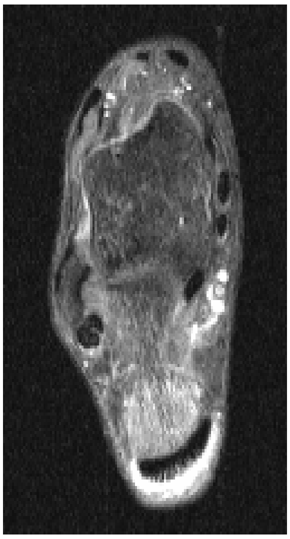
Peritendinita = inflamaţia peritenonului

Paratendinita = modificări inflamatorii în jurul tendonului

Ambele asociază modificări ale grăsimii preahilene Kager cu zone lineare sau difuze de semnal neomogen (determinate de edem sau de cicatrizarea peritenonului) cu sau fără morfologie anormală a tendonului.







Cazul 7

C.E. 18 ani

Acest pacient tânăr s-a prezentat la camera de gardă pentru un traumatism forte de picior drept. Examenul IRM a evidenţiat edem osos la nivelul calcaneului (hiposemnal T1 SE şi hipersemnal T1 SE FS) şi infiltraţie edematoasă peri- şi paratendinoasă la nivelul tendonului ahilean.

Tendinoza ahileană

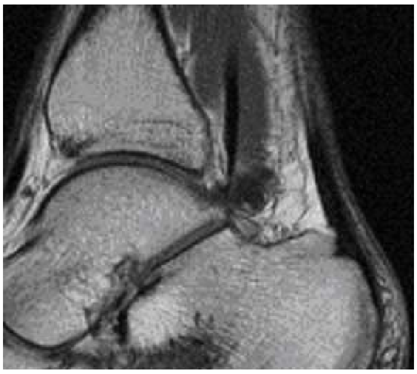
Modificări degenerative intratendinoase, fără substrat inflamator semnificativ. Clasificare:

1. degenerare fibromatoasă – îngroşarea tendonului, fără modificări de semnal;
2. degenerare mucoidă – îngroşarea tendonului şi semnal crescut IRM T1 şi T2 prin prezenţa depozitelor mucoide;
3. tendinopatie osoasă.

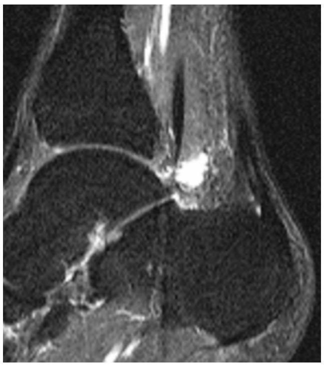
Cazul 8

P.I. 26 ani

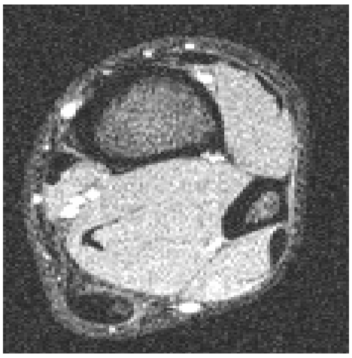
La nivelul tendonului lui Ahile se observă modificări de degenerare mucoidă deasupra inserţiei pe calcaneu (semnal intermediar T1SE şi crescut T1 TIRM şi T2 fl 2D)



T1 SE



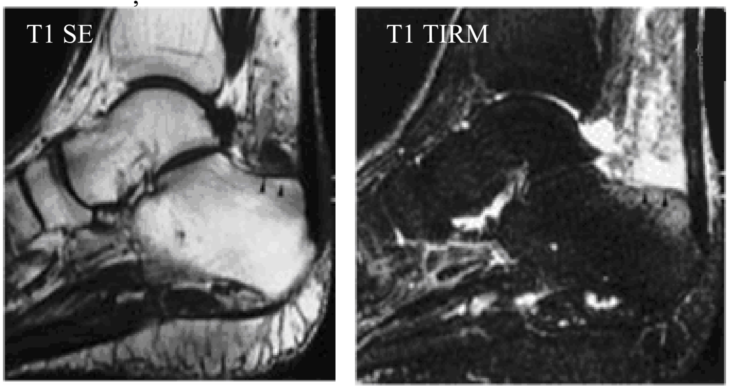
T1 TIRM



T2 fl 2D

Sindromul Haglund

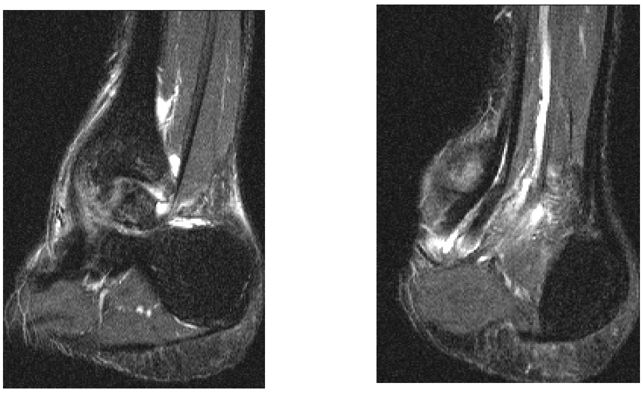
Reprezintă o particularitate a tendinozei ahilene ce cuprinde: tendinoza ahileană de inserție = îngroşarea focală a tendonului lui Ahile la inserția calcaneana; bursită retrocalcaneană; bursită calcaneană superficială; proeminența tuberozității posterioare a calcaneului; fracturi avulsie ale tuberozității calcanene.



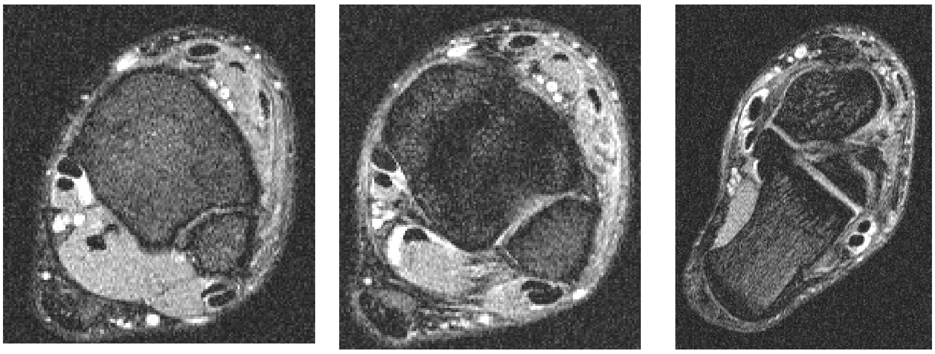
Cazul 9
I.C. 35 ani
Examenul IRM arată prezența tendinozei ahilene de inserție asociată cu bursita retrocalcaneeană, bursita calcaneeana superficială, proeminența tuberozității calcaneene şi edem osos la acest nivel.

Tenosinovitele. Afectează tendoanele şi fasciile lor. Se clasifică în: tenosinovite acute - fluid sinovial; tenosinovite cronice - fluid sinovial + îngroşarea tendonului cu semnal intermediar sau scăzut pe T2w; DD cu rupturile parțiale: pe secvențele cu TR şi TE lungi tendonul e în hiposemnal.

Cazul 10
C.B., 22 ani
Dg: Traumatism forte glezna dr.
IRM: Tenosinovita de TP, FLD, FLH, PL, PS, tendinită şi peritendinită cu ruptură parțială de tendon ahilean la inserția pe calcaneu.



T1 TIRM



T2 fl 2D

Cazul 11
M.A.S., 16 ani

Tendonul tibial anterior apare îngroşat şi manşonat de o zonă în hipersemnal.
Aspect sugestiv de tendinită cu tenosinovită de tibial anterior.
